La Metelli nasce il 1° Agosto 1962 quale officina per lavorazioni meccaniche. Nel 1970 prende avvio la produzione delle parti motore e già nel 1975 inizia la fabbricazione delle parti freno e frizione idrauliche. Un ulteriore impulso all'espansione giunge nel 1991 con l'installazione della linea per la produzione dei giunti omocinetiche a cui si aggiungono i semiassi nel 1999. Nel luglio del 2001 la Metelli S.p.A. acquista il 100% della società GRAF S.p.A., produttrice di pompe acqua e dischi freno. Nel 2008 vengono introdotte le pastiglie freno e nel 2010 le ganasce freno a completamento della gamma frenante. **Infine nel 2012 vengono lanciati il Kit distribuzione con pompa acqua e il kit cuffia.**

*Metelli was established on 1st August 1962 as a mechanical engineering workshop. In 1970, the company started producing engine parts and, in 1975, began manufacturing hydraulic brake and clutch parts. A further boost to expansion came in 1991 with the installation of the line for the production of constant velocity joints, later expanded in 1999 to include driveshafts. In July 2001, Metelli Co. acquired 100% of GRAF Co., a leading manufacturer of water pumps and brake discs. In order to complete the brake parts range Metelli introduced brake pads in 2008 and brake shoes in 2010. **Then in 2012 Metelli introduced the timing belt Kit with water pump and boot kit.***

*La société Metelli a été créée le 1er août 1962 comme atelier d'usinage. En 1970, l'entreprise a démarré la production de composants pour l'industrie des moteurs et a lancé en 1975 la fabrication de pièces de freinage et d'embrayage hydrauliques. En 1991, dans le cadre de sa politique d'expansion, la société a installé une nouvelle ligne pour la production de joints homocinétiques, à laquelle s'est ajoutée en 1999 celle des transmissions. En juillet 2001, Metelli S.p.A. a racheté la totalité de la société GRAF S.p.A., producteur leader de pompes à eau et de disques de frein. En 2008 nous avons introduits dans notre gamme les Plaquettes de Freins et en 2010 les Machoires de Frein à complètement de notre programme de freinage. **En 2012 nous avons introduits les kit distribution avec pompe à eau et les kit de soufflet de transmission.***

I motori a combustione interna ed il circuito di raffreddamento

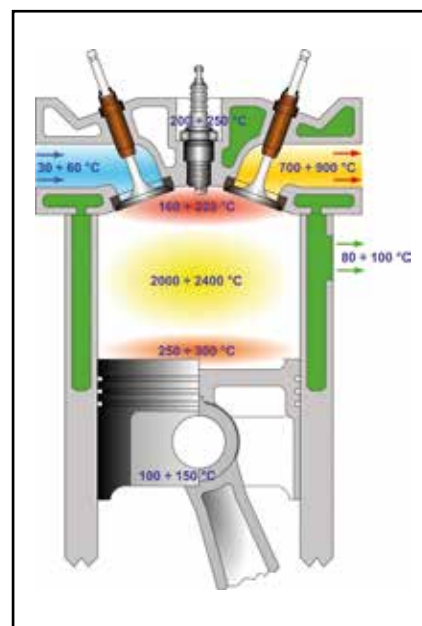

Ogni combustibile (gasolio, benzina, metano, ecc.) ha in sé una grande quantità di energia, questa è energia "chimica" che viene liberata sotto forma di pressione e calore durante la combustione.

All'interno del volume del cilindro chiuso tra la testa motore ed il cielo del pistone, si incendia la miscela di aria e combustibile trasformando l'energia chimica in calore e pressione (da qui il termine motore a combustione interna).

La particolare struttura meccanica del motore è in grado di trasformare l'energia liberata dallo scoppio in energia meccanica per il veicolo (o per altri scopi se per esempio il motore è un motore per applicazioni industriali).

Le temperature che si sviluppano all'interno della camera di combustione sono elevatissime, e tutto questo calore deve in qualche modo essere asportato; se così non fosse si arriverebbe ben presto prima ad un surriscaldamento del motore e poco dopo alla sua fusione. Per asportare il calore generato durante la combustione, tutto intorno al cilindro e nella testata ci sono un gran numero di canali nei quali scorre liquido di raffreddamento del motore.

Il liquido assorbe calore dalle pareti dei condotti scaldandosi ed il suo fluire lo porta poi a cedere il calore che porta con sé all'ambiente circostante mediante il radiatore (immagine 1.1).

1.1 Temperature nelle varie zone del motore

I motivi principali per cui i motori sono raffreddati a liquido sono due: potenze specifiche sempre più elevate, temperature di funzionamento sempre migliori.

Questi due fattori hanno contribuito già da tempo a fare convergere tutti i costruttori di motori verso soluzioni con raffreddamento a liquido, anche quei costruttori che storicamente avevano fatto scelte inizialmente diverse.

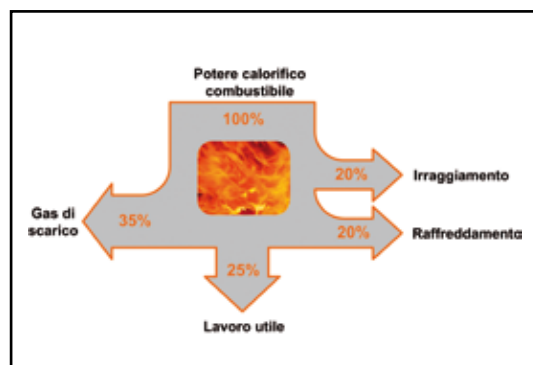

Raffreddare i motori mediante un liquido li rende più compatti (sono senza le ingombranti alettature tipiche dei motori raffreddati ad aria) ed in grado di funzionare a temperature più alte, migliorando complessivamente il rendimento.

Il calore generato dalla combustione del carburante nella camera di scoppio passa nell'ambiente circostante seguendo vie diverse: con i gas di scarico, per irraggiamento e conduzione verso l'ambiente che circonda il moto-

re stesso, ed infine attraverso il circuito di raffreddamento del motore (immagine 1.2).

Tenere sotto controllo la temperatura del motore è fondamentale, il buon funzionamento dello stesso dipende dal mantenimento della corretta temperatura; temperature troppo elevate compromettono la lubrificazione prima e successivamente i materiali del motore, mentre temperature troppo basse fanno lavorare il motore con eccessivi attriti e combustione non corretta.

Compito del circuito di raffreddamento del motore è quindi tenere sotto controllo la temperatura del motore curandosi sia del transitorio termico che dello smaltimento del calore prodotto all'interno del motore durante il funzionamento. I primi circuiti di raffreddamento non avevano nemmeno una pompa acqua per la circolazione for-

1.3 Vecchio motore privo di pompa acqua

zata, ma la generosa sezione dei tubi, unita ad un grande sviluppo verticale del radiatore, era sufficiente a generare una circolazione naturale dell'acqua sfruttando la differente densità alle diverse temperature (immagine 1.3).

Questo era possibile perché i motori di un tempo avevano potenze specifiche molto basse ed i volumi all'interno del cofano motore erano più che ampi. Le cose sono cambiate rapidamente con il passare del tempo, il design delle vetture, i motori stessi, gli spazi a disposizione, sono drasticamente diversi da quelli di un tempo.

I circuiti di raffreddamento dei motori moderni di conseguenza si sono dovuti adattare diventando più compatti, più efficienti e soprattutto tutti obbligatoriamente funzionanti con circolazione del refrigerante garantito dalla presenza di una pompa acqua (immagine 1.4).

I circuiti di raffreddamento dei motori moderni sono ormai dei veri e

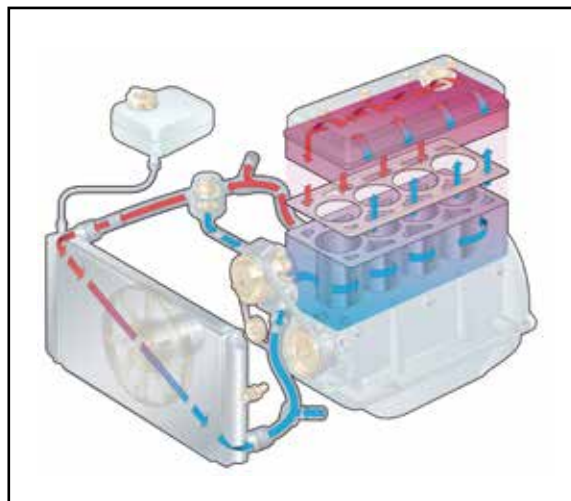

propri sottosistemi (di un certo grado di complessità) di un motore; componente principale del circuito è la pompa acqua che deve garantire la circolazione del liquido refrigerante in tutto il circuito.

Dato che i motori migliorano tanto più il loro rendimento complessivo se funzionano a temperature via via più alte, molti circuiti sono pressurizzati.

Questo significa che possono lavorare a temperature più elevate senza che il liquido di raffreddamento arrivi a bollire. Circuito pressurizzato vuol dire radiatori più piccoli, rendimento migliore del motore, ma anche temperature più elevate; i materiali di tutto il circuito devono essere attentamente scelti per resistere alle elevate tem-

perature di un circuito pressurizzato.

Dotati di uno o più radiatori, con circuiti secondari per il riscaldamento dell'abitacolo ed in alcuni casi dotati anche di un circuito per il raffreddamento della turbina, i circuiti di raffreddamento hanno il loro cuore nella pompa acqua.

1.4 Schema moderno circuito di raffreddamento

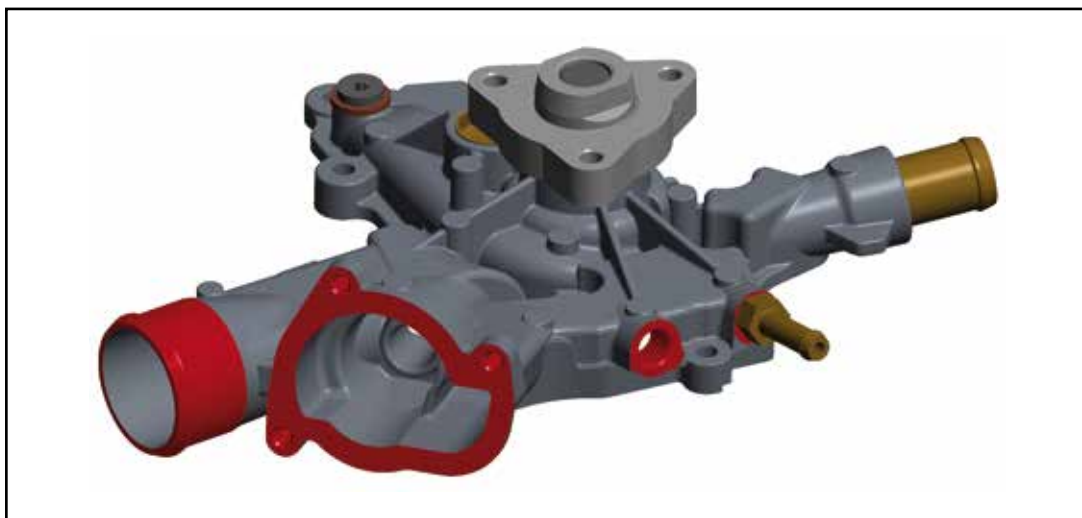

Funzionamento di una pompa acqua

Sebbene negli ultimi anni le pompe acqua abbiano subito importanti cambiamenti legati alle evoluzioni dei motori su cui sono montate, la grande maggioranza delle pompe acqua ha mantenuto una struttura "classica", le cui regole di progettazione non hanno subito drastici cambiamenti. Troviamo sempre una presa di moto meccanica, necessaria per trascinare in rotazione l'albero del cuscinetto interno a cui è collegata la girante che è il componente che trasferisce al flu-

ido la potenza meccanica che arriva dal motore.

I componenti ad alta specializzazione come la tenuta meccanica ed il cusci-

netto sono ormai molto industrializzati, costruiti con materiali altamente performanti che nel tempo si sono evoluti per durare sempre più a lungo e con-

temporaneamente resistere a temperature sempre più elevate.

È grazie all'azione della girante che il liquido di raffreddamento è in grado di vincere la resistenza del circuito di raffreddamento (di solito molto tortuoso), fluire e quindi essere in grado di trasferire calore dal motore al radiatore, che a sua volta lo cede all'ambiente esterno (immagine 2.1).

Così costruita la pompa acqua funziona fin dal primo istante in cui avviamo il motore anche quando non c'è effettiva necessità di far circolare il fluido. L'unico elemento che è in grado di fare in modo che l'acqua non passi per il radiatore è il termostato, la cui sede può trovare alloggiamento nello stesso corpo della pompa acqua (immagine 2.2). Grazie alla sua tecnologia costruttiva il termostato è fatto per aprire il flusso di refrigerante verso il radiatore soltanto dopo che è stata raggiunta una temperatura ben precisa; questo evita che

il refrigerante venga raffreddato quando in realtà non è ancora necessario (ad esempio quando il motore è ancora freddo).

Prendendo la potenza dalla cinghia del motore, o da altri meccanismi analoghi, la pompa acqua ha il suo nume-

ro di giri che è direttamente legato al numero di giri del motore; questo significa anche che la pompa acqua funziona fin dal primo momento che il motore si mette in moto anche se è freddo, ecco perché la presenza del termostato.

2.2 Moderno termostato

Prese di moto

La presa di moto di una pompa acqua è meccanica; questo significa che la pompa assorbe coppia dal motore per mettere in rotazione la girante che fa circolare il refrigerante, in che modo?

Nella maggioranza dei casi la pompa ha una puleggia che viene trascinata da una cinghia dentata, generalmente è la stessa cinghia che muove gli alberi a camme del motore (immagine 3.1).

In alcuni casi per esigenze legate al percorso della cinghia, la pompa acqua ha un puleggia senza dentatura perché il moto vie-

ne trasmesso soltanto per attrito con il dorso della cinghia stessa (immagine 3.2). L'impiego della cinghia di distribuzione non è l'unico caso nel quale la pompa acqua riceve la potenza dalla cin-

ghia, anzi ci sono una grande quantità di motori che, a causa del layout dei vari ausiliari hanno una cinghia dedicata esclusivamente a tutti questi servizi come ad esempio, la pompa olio del

servosterzo, la pompa da alta pressione del gasolio, il compressore del condizionatore, ed ovviamente anche la pompa acqua. In questi casi le cinghie impiegate per dare potenza ai servizi è di tipo Poly-V; più silenziosa e di più facile impiego rispetto alla cinghia dentata, è capace di garantire un funzionamento impeccabile ad ogni velocità di

3.3 Pompa acqua con presa di moto da una cinghia Poly-V

rotazione (immagine 3.3).

Come progettazione è stata ormai abbandonata la classica cinghia trapezoidale tipica dei motori di una certa età le cui prestazioni sono state ormai ampiamente superate dalla cinghia Poly-V. Le diversissime scelte progettuali che caratterizzano i motori moderni si riflettono anche nelle pompe acqua, tanto è

vero che le soluzioni per dare potenza ad una pompa acqua non si limitano alla sola cinghia motore (o alla cinghia servizi quando la distribuzione è mossa da una catena). Esistono infatti una serie di varianti nelle quali si ha un accoppiamento meccanico vero e proprio che fa uso di alberi con profili scanalati (immagine 3.4).

In realtà le soluzioni adottate sono anche diverse (ingranni, prese di moto sulla

catena di distribuzione, ecc.), ma si trovano veramente in pochi casi: in motori di una certa dimensione come quelli destinati ad applicazioni industriali (gruppi elettrogeni, ecc.) o motori per veicoli industriali.

Design di una pompa acqua

I fattori che concorrono a dare letteralmente forma ad una pompa acqua sono molti: prestazioni, affidabilità, lunga durata, unite ad una qualità complessiva ai massimi livelli sono le caratteristiche che cerchiamo durante lo sviluppo di ogni nostro prodotto. La geometria del corpo pompa è frutto non soltanto di considerazioni tecniche, legate alla sollecitazione a cui il corpo stesso è sottoposto, ma anche frutto della morfologia dell'intero circuito di raffreddamento.

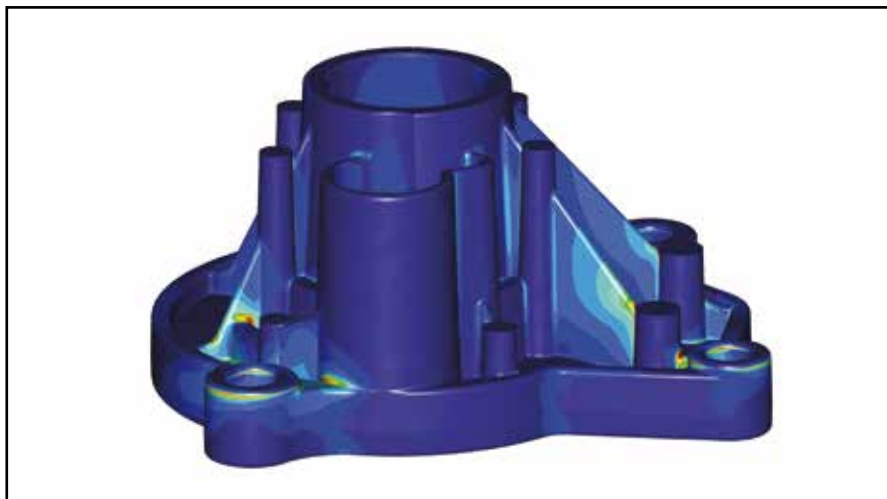

Spesso infatti la pompa acqua è in punto d'incontro dei circuiti "secondari" di circolazione del refrigerante quali riscaldamento abitacolo, raffreddamento turbina, ecc.

Inserite nella maggioranza dei casi in un vano direttamente nel basamento

motore, le pompe acqua si trovano ad operare in un ambiente gravoso; le alte temperature del liquido di raffreddamento e dell'aria sotto cofano, unite alle continue vibrazioni del moto-

re, costituiscono l'ambiente di lavoro abituale per una pompa acqua.

Tutto questo si riflette in un processo di design ad hoc per ogni specifico riferimento.

5.1 Analisi strutturale corpo pompa acqua

Ogni pompa acqua viene sviluppata secondo criteri comuni di progettazione affinati nell'esperienza aziendale che ormai ha raggiunto il mezzo secolo.

Analisi ad elementi finiti vengono effettuate per assicurarsi che le pompe acqua, sottoposte alla peggiore combinazione di condizioni di esercizio, sia ancora in grado di reggere le sollecitazioni mantenendo inoltre un adeguato margine di sicurezza ulteriore (immagine 5.1).

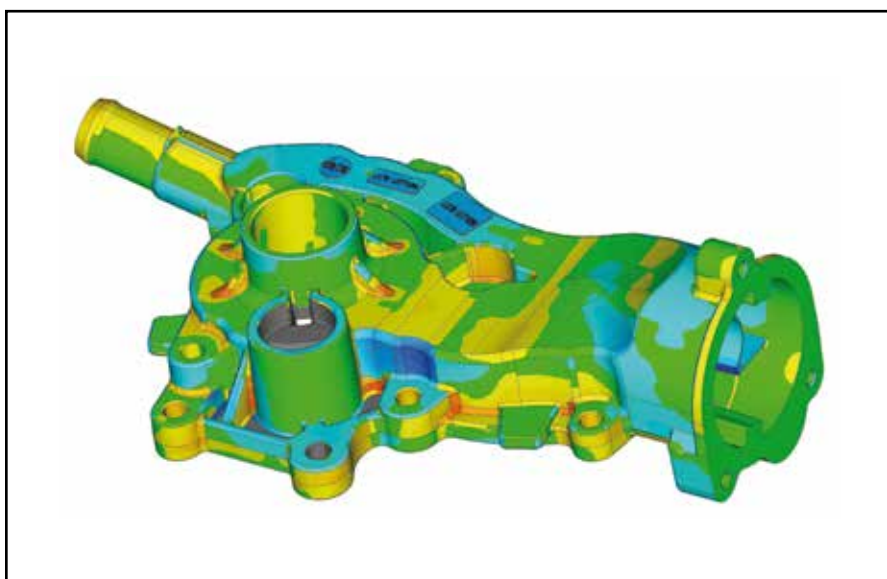

Spesso sulla pompa acqua sono montate una serie di masse rotanti aggiuntive (giunti viscostatici, ventilatori, ecc.); queste masse possono costituire un ulteriore aggravio delle condizioni di funzionamento della pompa (quando queste masse fossero diventate eccentriche).

Questo è un ulteriore aspetto del quale è necessario tenere conto in sede di dimensionamento; la presenza di

masse rotanti, che possono essere fonte di sollecitazioni aggiuntive, è fonte di un notevole incremento delle forze agenti sul corpo pompa che si sommano a quelle già presenti.

Il rigoroso rispetto delle dimensioni

imposte dal progetto è un altro aspetto cruciale, un completo controllo ottico effettuato in 3 dimensioni assicura che la geometria sia conforme a quanto stabilito in sede di progettazione (immagine 5.2).

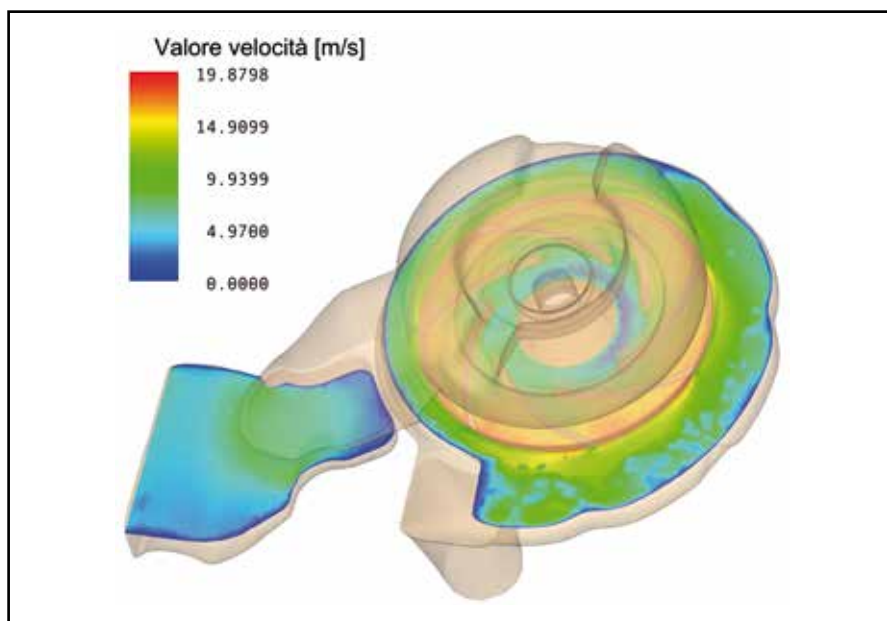

5.2 Controllo dimensionale 3D corpo pompa acqua

Il testing per assicurare le prestazioni della pompa acqua

La funzione primaria di una pompa acqua è garantire la circolazione del refrigerante in ogni parte del circuito; questo si traduce nel fatto che la pompa deve essere in grado di dare al fluido energia sufficiente per farlo circolare all'interno di tutti i condotti del circuito.

Le pompe acqua hanno un regime di rotazione che è strettamente vincolato al numero di giri del motore, quindi variabile; ciò significa che la pompa acqua deve fornire al refrigerante pressione e portata sufficienti in ogni sua condizione di funzionamento.

Per ottenere questo il componente principalmente responsabile è la girante che, assorbendo energia mec-

6.1 Analisi fluidodinamica di una pompa acqua

canica dall'albero del cuscinetto, la trasferisce al refrigerante sotto forma di energia cinetica.

Il design della girante e della voluta (quando questa costituisce parte integrante della pompa acqua) è strettamente connesso con le prestazioni fluidodinamiche risultanti.

Tali prestazioni vengono predeterminate mediante nostre procedure di calcolo; successivamente viene realizzato un modello 3D della girante così dimensionata e di tutta la geometria a contatto con il fluido (voluta, ecc.); quest'ultima viene poi verificata con programmi di simulazione.

Vengono effettuate infatti analisi fluidodinamiche con lo scopo di validare la geometria della girante calcolata e di poter avere una previsione delle prestazioni della pompa acqua in ogni condizione ritenuta significativa per il progetto, inclusa la verifica di assenza del fenomeno di cavitazione

nelle condizioni peggiori (immagine 6.1).

Una volta che i calcoli e le simulazioni hanno dato indicazioni sulla bontà della geometria, il tutto viene fisicamente realizzato mediante tecniche di rapid prototyping, che permettono di ottenere dei pezzi fisici in una particolare resina, partendo direttamente dal modello CAD 3D senza necessità di nessuna delle tradizionali attrezzature di produzione (immagine 6.2).

Per ogni singola pompa acqua destinata ad una prova di prestazioni, viene sviluppata, sulla base di calcoli fluidodinamici, un'ap-

6.2 Prototipo con componenti in resina di una pompa acqua

posita attrezzatura, il cui scopo è far lavorare la girante nelle condizioni corrette, solo in questo modo le prove effettuate danno dei risultati affidabili (immagine 6.3).

La possibilità di poter verificare l'insorgere o meno di certi fenomeni particolari è estremamente importante, per questo motivo con le attrezzature di prova vengono riprodotte in modo estremamente curato le condizioni di lavoro che la pompa incontrerà una volta montata nel motore (immagine 6.4).

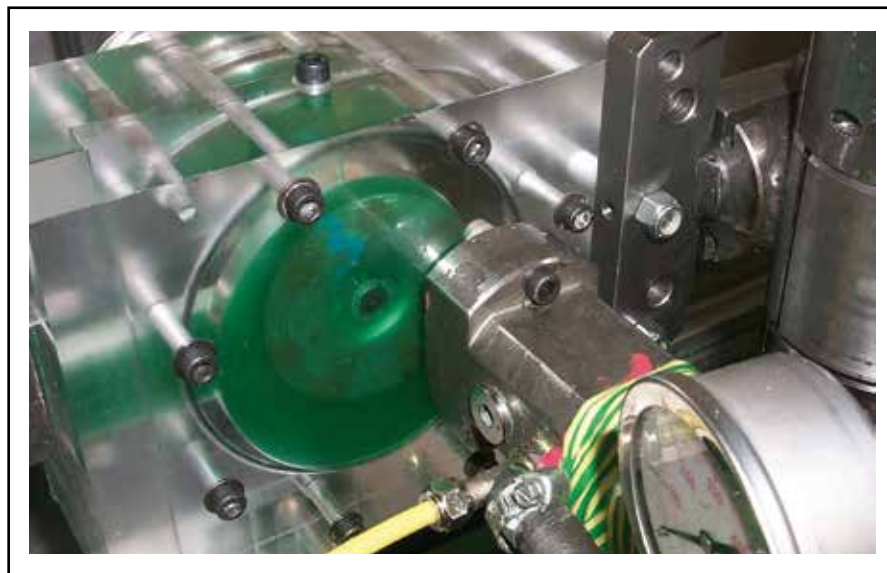

6.3 Attrezzatura di prova portata

I test reali, effettuati in condizioni strettamente controllate sui nostri banchi prova, tutti realizzati direttamente secondo nostre specifiche, danno evidenza finale sul buon esito dell'intero processo di progettazione. Questo ci assicura sull'effettivo rag-

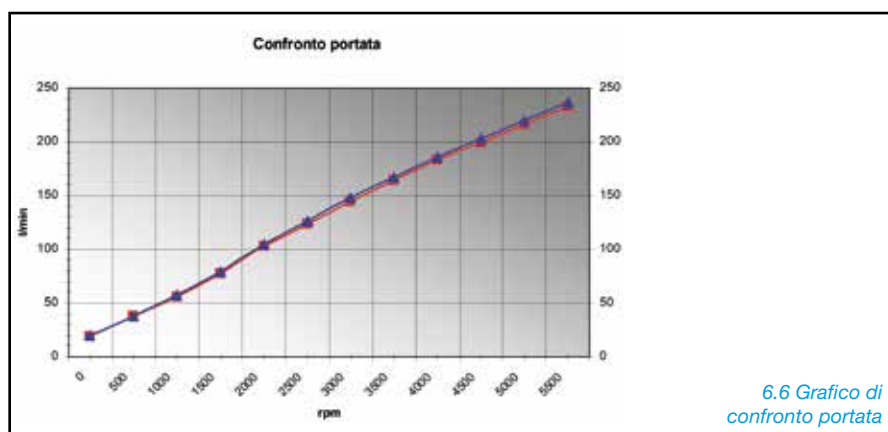

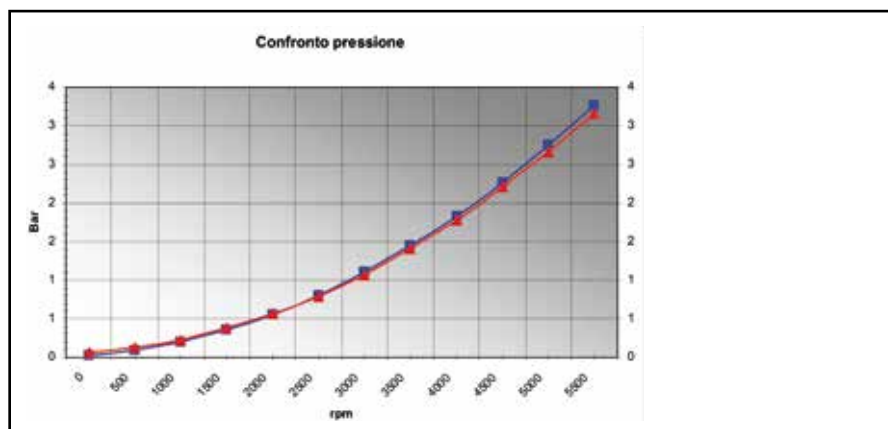

giungimento delle prestazioni idrauliche di progetto dei nostri prodotti in ogni condizione di possibile utilizzo (immagine 6.5).

La capacità di validare e testare adeguatamente i propri prodotti è fondamentale.

6.4 Attrezzatura di test trasparente

Forti della nostra lunga storia aziendale, abbiamo in house la capacità di eseguire un ampio insieme di prove ad ogni livello al fine di caratterizzare nel modo più completo il comportamento idraulico (e non solo) dei nostri prodotti (immagine 6.6).

6.6 Grafico di confronto portata

I liquidi refrigeranti

Nel circuito di raffreddamento del motore non è soltanto l'acqua che viene fatta circolare, tutt'altro! Quello che viene comunemente chiamato liquido refrigerante è una miscela in percentuali variabili (generalmente è però 50%-50%) di acqua ed una sostanza composta in prevalenza, ma non soltanto, da glicole etilenico.

I motivi di questa particolare miscela sono più di uno:

- Innalzamento del punto di ebollizione oltre la soglia normale dei 100°C a pressione atmosferica (il glicole etilenico puro infatti bolle a quasi 200°C).
- Abbassamento del punto di congelamento ben al di sotto della

7.1 Girante completamente corrosa a causa di liquidi non corretti

temperatura a cui l'acqua pura normalmente congela (i moderni liquidi antigelo abbassano il punto di congelamento fino a temperature di -30°C ed anche oltre).

- Aumento del calore specifico del liquido che permette, a parità di innalzamento della temperatura del fluido, di asportare una quantità maggiore di calore.

- Inibizione dei processi di corrosione che si possono innescare all'interno del motore.

Mentre da un lato il glicole etilenico ha influenza sulla modifica delle temperature di ebollizione, congelamento e sulla capacità del liquido di asportare calore, la protezione del circuito di raffreddamento dai fenomeni di corrosione merita un discorso a parte. Nel motore, e più in generale nell'intero circuito di raffreddamento, ci sono una grande varietà di metalli, ognuno di questi ha le sue caratteristiche chimiche e, messi a contatto fra di loro, possono innescarsi fenomeni di corrosione (immagine 7.1).

La presenza nel circuito di raffreddamento di un liquido che può contenere degli elementi chimici che favoriscono questo fenomeno porta ad un rapido degrado di alcuni componenti del circuito stesso (es. guarnizione

7.2 Due diversi liquidi refrigeranti

della testa, radiatore) con conseguenti problemi di varia natura.

Per evitare l'instaurarsi dei processi galvanici di corrosione, i moderni liquidi refrigeranti hanno delle sostanze apposite, che fungono da inibitori antiossidanti.

La presenza di queste sostanze conferisce ai liquidi refrigeranti molte proprietà utili al motore (inibitori della corrosione, inibitori del deposito di incrostazioni, proprietà antischiuma, ecc.) e sono anche il motivo per il quale tutti i liquidi hanno un loro colore particolare (immagine 7.2).

Una miscela di acqua e glicole etilico, sarebbe di per sé perfettamente trasparente, ma questi vengono colorati dai diversi produttori perché la presenza dei vari agenti inibitori, rende questi liquidi non sempre utilizzabili mescolati fra di loro.

Il motivo di ciò risiede nelle cosiddette basi degli inibitori, che possono

essere di tre differenti tipi: organiche, inorganiche e miste; queste basi sono chimicamente incompatibili le une con le altre e pertanto, sebbene la funzione di protezione del motore sia la stessa, nel circuito di raffreddamento deve essere utilizzato un liquido refrigerante che sia prodotto con lo stesso tipo di base dell'agente antiossidante.

I liquidi, dal punto di vista degli additivi inibitori che contengono, possono essere suddivisi in tre grandi gruppi principali:

- IAT= Inorganic Additive Technology (con additivi inorganici)
- OAT= Organic Acid Technology (con additivi ad acido organico)
- HOAT= Hybrid Organic Acid Technology (con additivi ibridi)

La colorazione data ai vari tipi di liquidi serve proprio ad evitare di fare miscugli di liquidi non compatibili fra loro che porterebbero alla formazione

di sostanze derivate da reazioni chimiche e l'effetto degli antiossidanti e degli inibitori di corrosione sarebbe annullato.

Va sottolineato che ogni produttore di liquidi refrigeranti ha adottato il proprio criterio di colorazione; questo significa che liquidi con uguale colore sono compatibili solo e soltanto quando sono dello stesso produttore!

Focus sui componenti principali

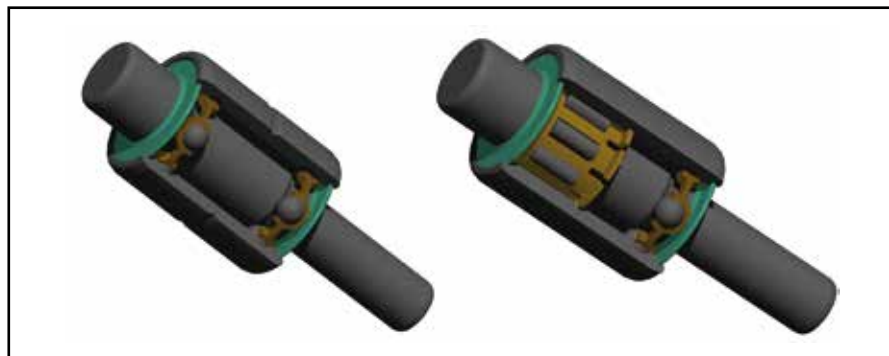

Ogni componente in una pompa acqua deve svolgere un compito ben preciso e deve quindi avere caratteristiche conformi a requisiti chiari. Sebbene anche la pompa acqua, come un qualunque altro organo meccanico, sia soggetta ad una normale usura, l'impiego di componenti di alta qualità, unito ad un processo di produzione sempre sotto rigoroso controllo, assicura un elevato grado di affidabilità ed una lunga durata del prodotto. Prima di introdurre un componente nuovo i nostri tecnici eseguono dei selettivi test di omologazione con lo scopo di assicurarsi che le prestazioni del componente siano in linea con le aspettative, soltanto dopo esito positivo il componente entra a far parte dei particolari che i progettisti possono impiegare in un nostro prodotto.

Cuscinetti

I cuscinetti sono direttamente responsabili di reggere i carichi che arrivano dalla tensione della cinghia. Nati come derivazione dei classici cuscinetti di uso comune, i cuscinetti per pompa acqua sono ormai progettati su dimensioni specifiche, e sono fatti per durare

quanto la vita attesa della pompa acqua, senza dover essere soggetti ad alcuna manutenzione.

Prodotti con già all'interno la giusta quantità di un grasso long-life e con i corpi volventi protetti da anelli di tenuta sia contro le perite di grasso che contro le infiltrazioni di acqua e sporco, i moderni cuscinetti per pompa acqua

8.1 Cuscinetto sfera-sfera e rullo-sfera

una volta montati nella pompa acqua non necessitano di alcun intervento di manutenzione.

Vengono assemblati per interferenza nel corpo e l'accurato controllo delle tolleranze dell'accoppiamento, unito al controllo in tempo reale delle forze di piantaggio, assicurano un accoppiamento ottimale con il corretto mantenimento del gioco radiale del cuscinetto (immagine 8.1).

Realizzati secondo due tipologie costruttive principali, si differenziano soprattutto per l'entità del carico che possono reggere.

I cuscinetti destinati a reggere i carichi più elevati, hanno infatti una delle due corone di corpi volventi costituite da rulli anziché dalle normali sfere; questo permette di aumentare la superficie di contatto tra i corpi volventi (i rulli) e le altre parti del cuscinetto e di conseguenza aumentano le forze che il cuscinetto è in grado di sopportare.

Giranti

Le giranti, sono i componenti che assicurano effettivamente le prestazioni idrauliche di una pompa acqua; sono specificatamente progettate e prodotte per garantire pressione e portata adeguate per il motore cui la pompa è destinata.

8.2 Modello 3D di una girante per pompa acqua

8.3 Giranti realizzati in modi differenti

La geometria di ogni girante, frutto di precisi calcoli, viene progettata a CAD fin nel minimo dettaglio e le sue prestazioni vengono poi verificate con i nostri banchi prova (immagine 8.2).

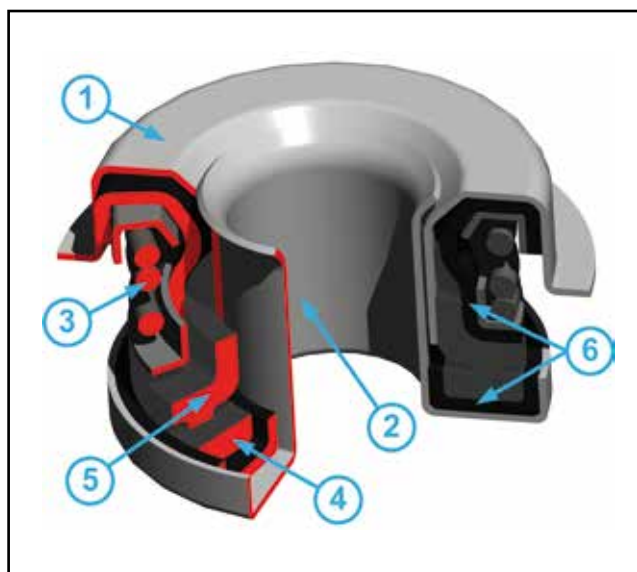

Realizzate con tecnologie che spaziano dalla lamiera (anche inox) tranciata ed imbutita, all'ottone pressofuso, alla ghisa fino ad arrivare ai più moderni tecnopolimeri, le giranti vengono di volta in volta prodotte con la tecnologia ritenuta più idonea per ottenere un componente che abbia sempre le migliori prestazioni fluidodinamiche possibili, senza per questo scendere mai a compromessi sull'affidabilità (immagine 8.3).

Questa libertà tecnica, derivata da un'esperienza lunga ormai mezzo secolo, ci permette avere grande libertà di scelta identificando il processo produttivo più adatto per ottenere la geometria di progetto.

Tenute meccaniche

La tenuta meccanica moderna è un componente altamente industrializzato, molto compatto e costruito interamente con materiali di alta qualità, è il componente che garantisce l'assenza

di perdite di liquido dalla pompa acqua. Indipendentemente dalle soluzioni tecniche dei dettagli i componenti che costituiscono la tenuta meccanica sono quasi sempre gli stessi (immagine 8.4):

1. Parte fissa
2. Parte rotante
3. Molla elicoidale
4. Anello di scivolo
5. Controfaccia
6. Guarnizioni

8.4 Sezione di una tipica tenuta meccanica

Può avere forma apparentemente diversa, ma il principio su cui si basa è il medesimo da sempre.

Lo sviluppo al quale è stato costantemente sottoposto negli anni, lo ha portato ad essere sempre più compatto ed avere una durata sempre maggiore; oggi la tenuta meccanica è in grado di reggere continuamente anche per molte decine di migliaia di chilometri (immagine 8.5).

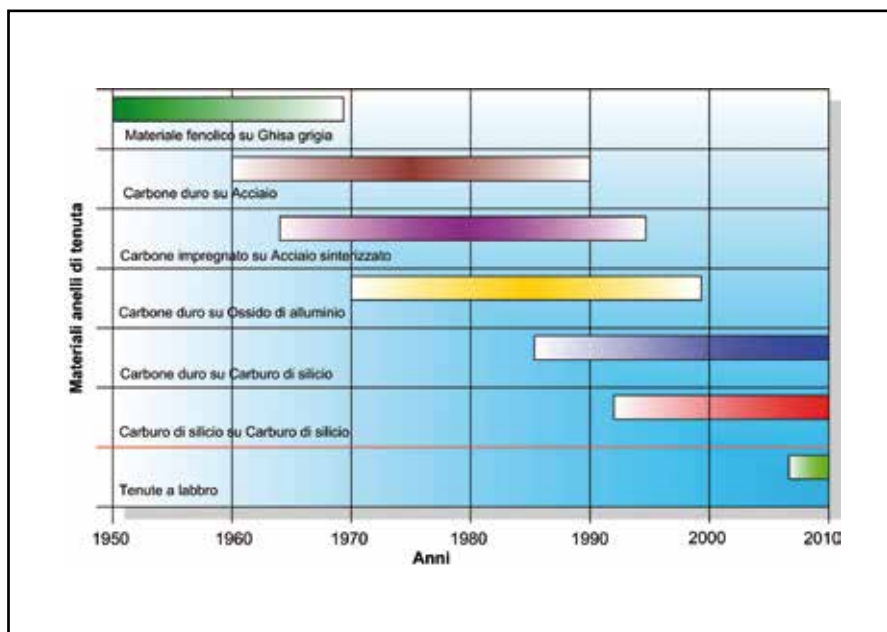

Materiali estremamente duri come il Carburo di Silicio che fino ad alcuni

8.5 Alcuni tipi di tenute meccaniche

anni orsono erano considerati “esotici”, sono al giorno d’oggi ritenuti normali per le realizzare gli anelli di scivolo di tutte le moderne tenute meccaniche di qualità; questo grazie

ad un continuo impegno nello sviluppo dei materiali di questi componenti (immagine 8.6).

8.6 Storia dei materiali degli anelli usati nelle tenute meccaniche

Mozzi e pulegge

Le pulegge, che ricevono la potenza meccanica dalla cinghia o in rari casi dalla catena, sono i componenti che tengono effettivamente in rotazione l'alberino del cuscinetto e di conseguenza la girante.

I mozzi svolgono la medesima funzione, vengono impiegati quando, per ragioni progettuali, l'ingombro della puleggia è superiore alla zona in cui ci sono i fori di fissaggio della pompa acqua nella sua sede; dal punto di vista funzionale sono considerabili alla stessa stregua.

Montati per interferenza sulla parte superiore dell'alberino del cuscinetto, devono essere perfettamente fissati per reggere le sollecitazioni che arrivano dalla cinghia del motore (immagine 8.7).

La geometria esterna delle pulegge è fatta secondo tolleranze rigorose;

solo in questo modo si è in grado di garantire il perfetto accoppiamento tra puleggia e cinghia; questo si traduce in un funzionamento esente da vibrazioni e rumore ed una vita della cinghia in linea con i migliori standard.

8.7 Mozzi e pulegge per pompa acqua

Corpi pompa

Il corpo principale della pompa acqua, realizzato nella grande maggioranza dei casi in lega di alluminio, deve contemporaneamente assolvere a diversi compiti.

- Deve essere in grado di sopportare le tutte sollecitazioni meccaniche
- La fusione deve essere perfettamente a tenuta stagna in quanto il corpo è parte integrante del circuito di raffreddamento
- Deve accoppiarsi correttamente con l'interfaccia sul basamento motore e garantire la perfetta tenuta al fluido
- Deve alloggiare correttamente il cuscinetto e la tenuta meccanica con le corrette tolleranze

8.8 Modello 3D di un corpo pompa acqua

È fuori di dubbio che è il componente che richiede maggior perizia nel suo sviluppo, anche perché ogni corpo pompa costituisce letteralmente un vero e proprio caso a sé stante (immagine 8.8).

Istruzioni ed accorgimenti per un corretto montaggio

Le operazioni di installazione di una pompa acqua in sostituzione di una a fine vita, devono essere eseguite con cura, avendo accortezza di eseguire il tutto nel migliore modo possibile e non dimenticandosi di fare tutte le verifiche necessarie anche relativamente ai componenti direttamente correlati alla pompa acqua.

1. Operare sempre in condizioni di sicurezza e nel rispetto dell'ambiente.

2. **Rendere accessibile l'area di lavoro**, se necessario rimuovere i pezzi necessari per accedere correttamente alla zona della pompa acqua.

3. Se ci sono particolari prescrizioni del costruttore per il montaggio della pompa acqua, **attenervisi scrupolosamente**.

4. Il circuito di raffreddamento deve essere **svuotato completamente**, accu-

ratamente pulito e risciacquato; particelle presenti nel circuito rovinano le facce degli anelli di tenuta, pregiudicandone il funzionamento in poco tempo.

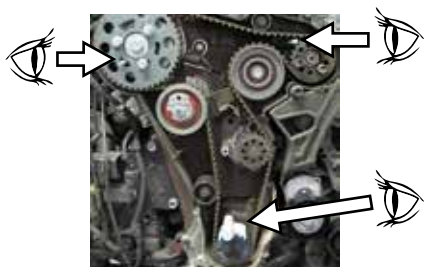

5. Il liquido refrigerante va interamente sostituito con un **liquido nuovo, che risponda pienamente alle caratteristiche richieste dal costruttore**.

6. Se la pompa acqua è parte del circuito della distribuzione, la prima operazione da effettuare è il **bloccaggio della fase del motore utilizzando gli utensili speciali ove previsti dal costruttore**.

2014

7. Una volta che la pompa è stata rimossa, si deve **pulire molto bene la superficie del basamento motore** da residui di pasta sigillante, pezzi di guarnizione rimasti incollati, riportando la superficie metallica perfettamente pulita, sgrassata ed asciutta.

8. Controllare prima di ogni altra cosa che la pompa in sostituzione sia intercambiabile con quella nuova.

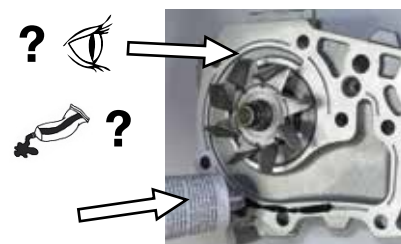

9. Se la **pompa ha una guarnizione, metallica o di altro tipo, la pasta sigillante non va assolutamente utilizzata**; la guarnizione fornita con la pompa è adeguata per garantire una perfetta tenuta.

nuta, curare bene la pulizia della superficie di montaggio sul basamento motore.

10. Nel caso in cui la pompa preveda un'installazione con la pasta sigillante, avere sempre cura di stenderne, solo ed esclusivamente sulla superficie della pompa acqua, la quantità corretta **senza eccedere**; la pasta in eccesso infatti va spesso a finire nella tenuta meccanica causando perdita.

11. Ogni guarnizione che è stata smontata, va sostituita con una nuova; mai riutilizzare guarnizioni usate anche se sembrano in buone condizioni.

12. Le viti di fissaggio vanno avvitate incrociate e, prima di serrarle completamente, **ci si deve assicurare che la pompa sia centrata correttamente e possa girare liberamente** nella sua sede.

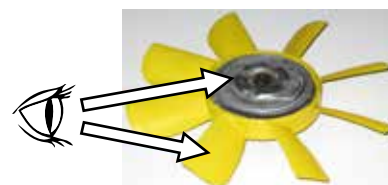

13. Rispettare scrupolosamente i valori di coppia di serraggio delle viti indicate dalla casa costruttrice.

14. Attendere sempre circa 1 ora con il circuito di raffreddamento vuoto per permettere al sigillante che è all'interno della voluta di polimerizzare correttamente.

15. Verificare il buono stato di eventuali giunti (viscostatici e di altro genere) **montati sulla pompa acqua** nonché delle relative ventole; se si trovano giunti viscostatici con giochi non usuali o ventole storte o mancanti anche solo di parti di una pala, questi componenti vanno sostituiti.

16. Le fascette stringi tubo che sono state rimosse vanno controllate ed eventualmente sostituite con fascette nuove.

17. Contestualmente alla sostituzione della pompa acqua, oltre alla cinghia, vanno sostituiti tutti i componenti interessati dalla cinghia stessa (galoppini, rulli e/o cilindri tenditori ed altri organi legati al sistema).

18. Posizionare la cinghia seguendo correttamente le prescrizioni del costruttore, soprattutto quando si tratta della cinghia di distribuzione; se sono stati previsti degli utensili speciali, usarli.

19. Alcune pompe acqua hanno ingranaggi ed alberi scanalati come presa di moto; assicurarsi del buono stato delle

dentature e, per gli alberi scanalati, avere l'accortezza di mettere una piccola quantità di grasso specifico sulla scanalatura prima dell'inserimento in sede.

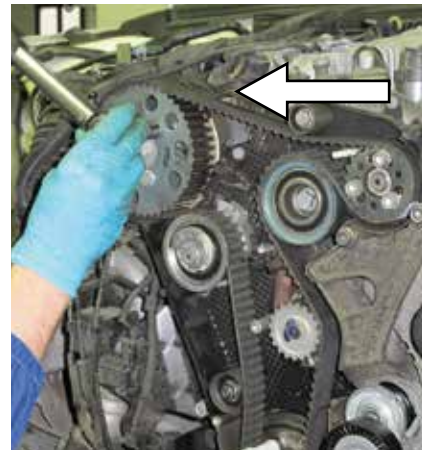

20. Verificare lo stato ed il corretto funzionamento del termostato.

21. Verificare il funzionamento delle sonde di temperatura.

22. Verificare il buono stato del tappo del vaso di espansione; non deve essere incrostate.

23. Se prima di smontare la cinghia di distribuzione gli alberi del motore non sono stati bloccati è **indispensabile ripristinare la corretta fase del motore** seguendo scrupolosamente le operazioni raccomandate dal costruttore.

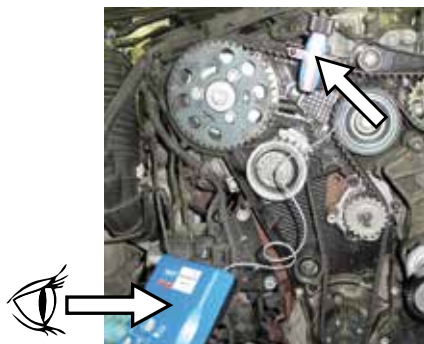

24. Tendere la cinghia rispettando il valore raccomandato dal costruttore; evitare tensioni eccessive, far girare il motore manualmente e verificare che

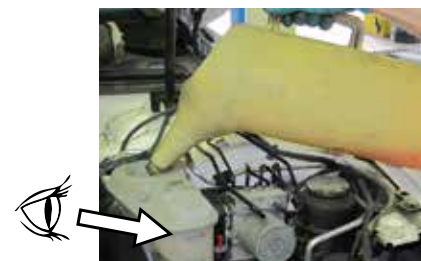

la posizione della cinghia sia stabile; eventualmente ripristinare poi la tensione corretta.

25. Per controllare la tensione della cinghia **utilizzare strumentazioni appropriate** che siano in grado di fornire dati certi sul valore di tensione applicato.

26. Una volta installata la pompa e sigillato nuovamente il circuito, provvedere ad un suo primo riempimento con un liquido refrigerante conforme a quanto raccomandato dal costruttore.

27. Accendere il motore e, lasciato al minimo, accendere il riscaldamento abitacolo e continuare a rabboccare il liquido refrigerante dal punto più alto del circuito (generalmente il vaso di espansione) fino a che il livello non cala più, attendere l'apertura del termostato in modo da riempire correttamente anche il radiatore.

28. Avere cura di lasciare meno aria possibile nel circuito ancora prima di avviare il motore; il funzionamento anche per pochi secondi della pompa acqua a secco rovina la tenuta meccanica, causando un suo successivo funzionamento rumoroso e/o perdite di liquido.

I casi più comuni di danneggiamento di una pompa acqua: cause ed analisi

Una preparazione sul motore dell'area che è destinata ad accogliere la pompa acqua, unita all'esecuzione a regola d'arte delle operazioni di montaggio, sono passi fondamentali affinché la pompa, una volta in esercizio, si comporti come ci si aspetta.

Evitare di incorrere in una serie di errori comuni legati alle operazioni di installazione eseguite in modo non corretto, evita il verificarsi di inconvenienti banali ma fastidiosi, vediamo quali.

Liquidi di raffreddamento non idonei

L'impiego di liquidi di raffreddamento non idonei, non soltanto può creare

problemi al motore dal punto di vista termico, ma peggio ancora non pro-

10.1 Componenti arrugginiti a causa di liquidi non idonei

tegge dai fenomeni di corrosione che possono instaurarsi nell'intero circuito. Questo è causa di una corrosione di tutti i metalli del circuito, secondo la loro attitudine chimica; il risultato è un rapido degrado di tutte le superfici del circuito di raffreddamento. L'impiego di liquidi non idonei, inquinati, o contaminati da particelle, è causa, oltre che

di corrosione, anche di durata limitata della tenuta meccanica.

Le perdite di liquido si vanno ad accumulare a ridosso del cuscinetto, provocando spesso la fuoriuscita del grasso ed il conseguente cedimento del cuscinetto (immagini 10.1 e 10.2).

Bolle d'aria residue nel circuito

Eliminare completamente le bolle d'aria dal circuito di raffreddamento è molto importante. Le bolle d'aria residue che non riescono a finire nel vaso d'espansione superiore fanno, nella migliore delle ipotesi, lavorare il circuito a sezione ridotta; la presenza di bolle d'aria che non si eliminano può compromettere il buon funzionamento della pompa acqua (immagine 10.3).

10.2 Tenute meccaniche rovinate da liquidi non idonei

10.3 Traccia di funzionamento con una bolla d'aria presente

Surriscaldamento

Quando l'aria è presente in quantità nel circuito, la tenuta meccanica funziona a secco; questo ha come primo effetto quello di lucidare a specchio le superfici degli anelli di tenuta causando successivamente perdite, e se il fenomeno dura nel tempo il calore

sviluppato è tale da fondere le parti in gomma della tenuta e lasciare traccia del calore anche sul corpo stesso della pompa (immagine 10.4).

Sbilanciamento giunto viscostatico

È importante assicurarsi che il giunto viscostatico sia in perfette condizioni prima di rimontarlo sulla pompa acqua. Un viscostatico con il cuscinetto danneggiato gira sbilanciato e di conseguenza rappresenta una forte sol-

lecitazione che si aggiunge al carico della cinghia. Questo porta facilmente al cedimento del cuscinetto della pompa acqua (immagine 10.5).

Nei casi di sbilanciamento più gravi, le sollecitazioni raggiungono valori talmente elevati da provocare addirittura la rottura del corpo pompa (immagine 10.6).

Sostituzione altri componenti del sistema di trascinamento

La grande maggioranza delle pompe acqua prende il moto da una cinghia, distribuzione o servizi che sia. La prima cosa da fare è un accurato esame dello stato della cinghia, se presenta segni di usura o di invecchiamento del materiale (crepe nella gomma, superfici lucide, ecc.), va sicuramente

cambiata. Sostituendo la pompa acqua sarebbe sempre bene sostituire i galoppini ed i tenditori che, quando hanno malfunzionamenti, sono spesso causa del cedimento del cuscinetto della pompa acqua come conseguenza di un sovraccarico nella tensione della cinghia (immagine 10.7).

Sovraccarico cuscinetto

La tensione della cinghia con valori di carico oltre quelli raccomandati è causa di condizioni di lavoro del cuscinetto particolarmente gravose. Il risultato è una vita del componente estremamente ridotta ed in alcuni casi si arriva ad un cedimento completo dello stesso (immagini 10.8 e 10.9).

10.8 Albero cuscinetto danneggiato per carico eccessivo

10.9 Componenti cuscinetti danneggiati per sovraccarico

Utilizzo scorretto della pasta sigillante

L'impiego della pasta sigillante, è previsto su alcuni riferimenti, e su questi deve essere usato nel modo corretto. Vanno sempre utilizzati prodotti specifici, mai sigillanti generici o di altra natura ed è altrettanto importante che vengano utilizzati nella corretta quantità. L'impiego di sigillanti non idonei e peggio ancora in quantità eccessiva è sempre causa di problemi; accumuli di sigillante residuo che finisce nella tenuta meccanica cau-

10.10 Uso scorretto di materiale sigillante

sano immediatamente perdite e ci possono essere grumi di sigillante indurito che finiscono nei condotti del circuito di raffreddamento (immagine 10.10).

Se una pompa acqua è stata prevista una guarnizione metallica, O-ring, o altro, questa soluzione è sufficiente a garantire la tenuta; non si deve applicare la pasta sigillante, comprometterebbe soltanto il funzionamento della guarnizione fornita con il pezzo (immagini 10.11 e 10.12).

10.11 Pasta sigillante erroneamente applicata su guarnizione metallica

10.12 Pasta sigillante erroneamente applicata su guarnizione O-ring

Montaggio non corretto

È importante che le operazioni di montaggio della pompa acqua nella sua sede vengano fatte nel modo corretto, seguendo attentamente le eventuali istruzioni particolari in allegato.

10.13 Danni causati da montaggio non corretto

Un montaggio eseguito in modo non corretto può facilmente portare la pompa acqua a lavorare male o peggio danneggiare alcuni componenti siano essi delicati come le guarnizioni, o

in certi casi addirittura il corpo stesso della pompa acqua (immagine 10.13).

Montaggio di componenti sulla pompa acqua

Alcune pompe acqua portano montati altri componenti che devono venire installati dopo che la pompa acqua è stata installata sul motore. Eseguire correttamente le operazioni di montaggio di tali componenti è fondamentale; in particolare è estremamente importante evitare ad ogni costo di dare colpi di qualunque genere all'alberino del cuscinetto, questo causa come minimo il danneggiamento delle gole di scorrimento delle sfere del cuscinetto e in alcuni casi si può arrivare alla rottura dell'alberino stesso (immagine 10.14).

Corpi estranei nel circuito

Eeguire un'accurata pulizia di tutto il circuito quando si sostituisce la pompa acqua. È possibile che vi siano dei corpi estranei all'interno del vano di alloggiamento che, quando vengono spostati dal flusso di refrigerante, possono causare inconvenienti notevoli.

Quando la girante incontra un corpo estraneo si danneggia irrimediabilmente, creando potenziali problemi non solo a tutto il circuito di raffreddamento, ma è possibile che si verifichino danni anche alla distribuzione (immagine 10.15).

Tendenze

Mai come negli ultimi anni si assiste ad un processo innovativo legato a questo componente i cui criteri progettuali sono rimasti immutati per decenni. Le esigenze di riduzione di consumi ed emissioni, la necessità di contenere il peso dei componenti, la sempre maggiore durata richiesta ai prodotti, hanno fatto cambiare la pompa acqua in molti suoi aspetti ed hanno fatto nascere un'intera nuova generazione di pompe acqua nate da concetti di progettazione integralmente nuovi.

Materiali

Accanto ai materiali ritenuti più "tradizionali" come ad esempio l'alluminio pressofuso per i corpi pompa, si as-

siste ad una sempre maggior introduzione di tecnopolimeri. Materiali simili a quelli ormai visti spesso impiegati nelle giranti, sempre di più negli ultimi anni hanno trovato impiego nella realizzazione del corpo della pompa acqua (immagine 11.1).

Caratterizzati da un peso contenuto, da una buona stabilità dimensionale e da un'ottima compatibilità chimica, l'introduzione di questi materiali nei corpi pompa acqua è ancora limitata ad un ristretto numero di riferimenti.

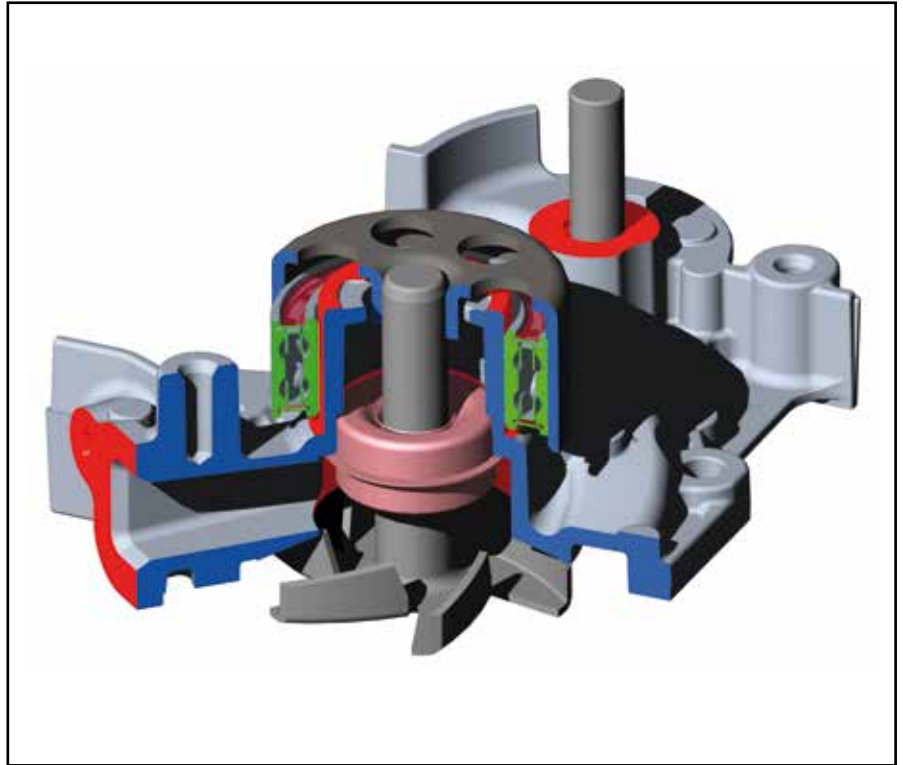

11.1 Corpo pompa in materiale termoidurente

Cuscinetti

Accanto ai cuscinetti specifici per pompa acqua che il mercato è abituato a vedere da molti anni, a causa dei continui incrementi di potenza che i motori subiscono durante la loro vita sul mercato, le cinghie sono sempre più sollecitate ed hanno reso necessaria l'introduzione di una generazione nuova di cuscinetti, più simili ai cuscinetti che si trovano nelle pulegge dei compressori dei condizionatori (immagine 11.2).

A differenza dei cuscinetti da montare all'interno della sede nel corpo pompa, questi cuscinetti sono da montare esternamente al corpo; questo permette di avere un cuscinetto di dimensioni maggiori che è in grado di reggere sollecitazioni più elevate e quindi di garantire un funzionamento senza problemi anche il quei motori che durante la loro evoluzione hanno visto aumentare considerevolmente i valori della tensione delle cinghie.

Tenute

Le tenute meccaniche monoblocco hanno negli anni subito una costante evoluzione nella geometria e nei materiali impiegati specialmente negli anelli di tenuta; questo progresso le ha rese sempre più compatte e contemporaneamente più durevoli.

Recentemente ha fatto la sua comparsa sul mercato un'intera generazione di tenute meccaniche di nuova concezione (immagine 11.3).

Più simili agli anelli di tenuta olio che alle tenute meccaniche classiche, questa nuova generazione di componenti ha la tenuta lungo la superficie dell'albero del cuscinetto. Dotate di una maggior resistenza al funzionamento a secco, e di una coppia resistente inferiore, sono tenute che impiegano soluzioni e materiali innovativi e grazie alla loro geometria hanno ingombri veramente ridotti ai minimi termini.

Soluzioni

Le tendenze di sviluppo odierne stanno portando sul mercato una vasta tipologia di pompe acqua, di concezione nuova, il cui scopo è quello di venire incontro alle nuove esigenze di efficienza della pompa stessa e di riduzione emissioni dei motori.

Per sua naturale caratteristica, una pompa acqua tradizionale è progettata per smaltire il calore prodotto dal motore quando questo sta funzionando al massimo delle sue prestazioni. Questo regime di funzionamento è, nella reale condizione di utilizzo del motore, molto poco frequente; per un motore automobilistico le massime prestazioni sono chieste al motore meno del 10% della sua intera vita.

Le soluzioni che i progettisti hanno elaborato per venire incontro all'esi-

12.1 Sezione della pompa acqua azionabile brevettata da Metelli

genza di avere una pompa acqua che sia adeguata per un corretto raffreddamento del motore, ma maggiormente ottimizzata per rispondere alle molteplici esigenze di un moderno motore, sono molto diverse fra loro.

Queste soluzioni hanno fatto nascere una famiglia di pompe acqua di nuova generazione denominate azionabili; un'intera serie di soluzioni che, pur sempre prendendo il moto dalla cinghia, sono in grado di interrompere il flusso d'acqua utilizzando varie soluzioni differenti.

Alcune di esse impediscono la circolazione dell'acqua mediante la chiusura dei passaggi nella pompa stessa, mentre altre scollegano la puleggia fermando la rotazione della girante.

Metelli ha sviluppato perfezionando la sua soluzione; una soluzione innovativa, per la quale è stato ottenuto il brevetto europeo, che rappresenta

ad oggi la soluzione più affidabile presente sul mercato.

Questa soluzione permette di interrompere la circolazione del fluido nel circuito di raffreddamento utilizzando una serranda azionata pneumaticamente. L'azionamento della serranda avviene creando una depressione all'interno di una specifica zona del corpo pompa, detta "zona del vuoto"; il motivo di questa denominazione sta nel fatto che viene utilizzato la depressione prodotta dalla pompa a vuoto del servofreno.

Questa soluzione vista dall'esterno di presenta come una pompa acqua apparentemente normale, con il corpo più ingombrante intorno alla zona del cuscinetto; proprio dentro questo ingombro alloggia tutto il meccanismo che serve a movimentare la serranda che si trova intorno alla girante.

Questo meccanismo, potenzialmente dannoso per il motore dato che è in-

fatti in grado di interrompere il flusso dell'acqua nel circuito di raffreddamento, è stato sviluppato in modo da essere "fail safe" cioè tale da lasciar passare sempre il fluido anche in caso di suo malfunzionamento, tutto a vantaggio di una soluzione proposta all'insegna dell'affidabilità.

È in atto una vera e propria rivoluzione nel modo di concepire un prodotto che è rimasto immutato nella sua sostanza per 40 anni.

Questi nuovi approcci alla progettazione della pompa acqua hanno cominciato a portare sul mercato un'intera nuova generazione di prodotti più sofisticati, più efficienti e con prestazioni più in linea con le esigenze dei motori moderni.

Internal combustion engines and their cooling circuits

All fuels (diesel, petrol, methane, etc.) contain a large amount of energy, this energy is “chemical” and is released in terms of pressure and heat during combustion.

Within the cylinder volume, enclosed between the motor head and the piston's upper surface, the mixture of air and fuel ignites, transforming chemical energy into heat and pressure (hence the term internal combustion engine).

The particular mechanical structure of the motor is able to transform the energy released by the combustion into mechanical energy for the vehicle (or for other purposes if for example the engine is an engine for industrial applications).

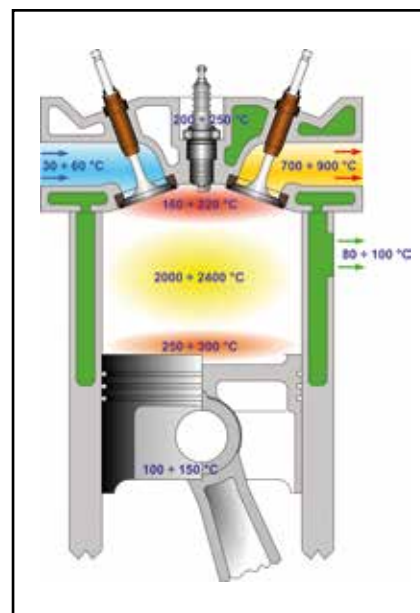

The temperatures generated inside the

combustion chamber are extremely high, and this heat must somehow be removed, if not the first result would be an overheating engine, and shortly thereafter its meltdown.

In order to remove the heat generated during combustion, all around the cylinder and inside the cylinder head there are a large number of channels in which the engine coolant flows (image 1.1).

The liquid absorbs heat from the walls of the ducts warming up and as it flows it transfer this heat to the surrounding environment through the radiator.

There are two main reasons for engines to be liquid-cooled: increasingly elevated power density, increasingly higher operating temperatures.

1.1 Temperatures in the various areas of the engine

These two factors have, for some time, been the main reasons for engine manufacturers moving towards solutions with liquid cooling systems, even those manufacturers who historically had initially made different choices. Cooling engines by means of a liquid makes them more compact (without the bulky cooling fins that are typical of air-cooled engines) and capable of operating at higher temperatures, improving overall efficiency.

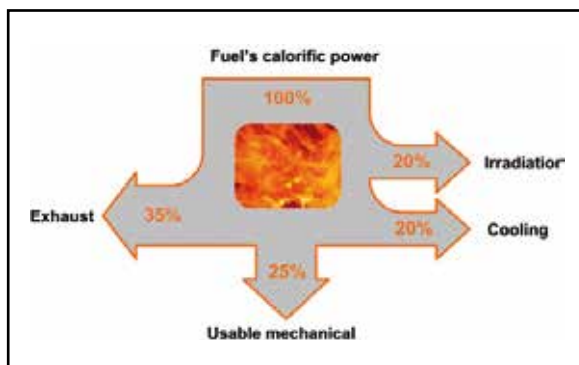

The heat generated by fuel combustion in the combustion chamber goes to the surrounding environment by following different routes: in the exhaust fumes, by radiation and conduction to the environment surrounding the motor itself, and finally through the engine's cooling circuit (image 1.2).

Monitoring the temperature of the engine is important, the proper functioning thereof depends on maintaining the correct temperature;

temperatures that are too high firstly compromise lubrication and then the engine materials themselves, while temperatures that are too low make the engine work with excessive friction and incorrect combustion.

The task of the engine cooling circuit is therefore to keep the temperature of the engine under control, handling the thermal transient and the disposal of heat produced inside the engine during operation.

The first cooling systems did not even have a water pump for forced circulation, but the wide section of the pipes, combined with a great vertical development of the radiator, was enough to generate a natural flow of water by exploiting the difference in density at different temperatures (image 1.3).

1.2 Internal combustion engine efficiency

1.3 Old engine without water pump

This was possible because the engines of the past had a very low power density and the volume inside the engine hood was extremely wide.

Things changed rapidly with the passing of time, the design of the cars, the engines themselves, the space available, are drastically different from those of the past.

The cooling circuits of modern engines therefore have had to adapt becoming more compact, more efficient and above all they must operate with coolant circulation guaranteed by the presence of a water pump (*image 1.4*).

The cooling circuits of modern engines are now real subsystems (with a certain degree of complexity); main component of the circuit is the water pump that has to guarantee the circulation of coolant throughout the whole circuit.

Since the engines improve their overall performance especially when operating at higher and higher temperatures,

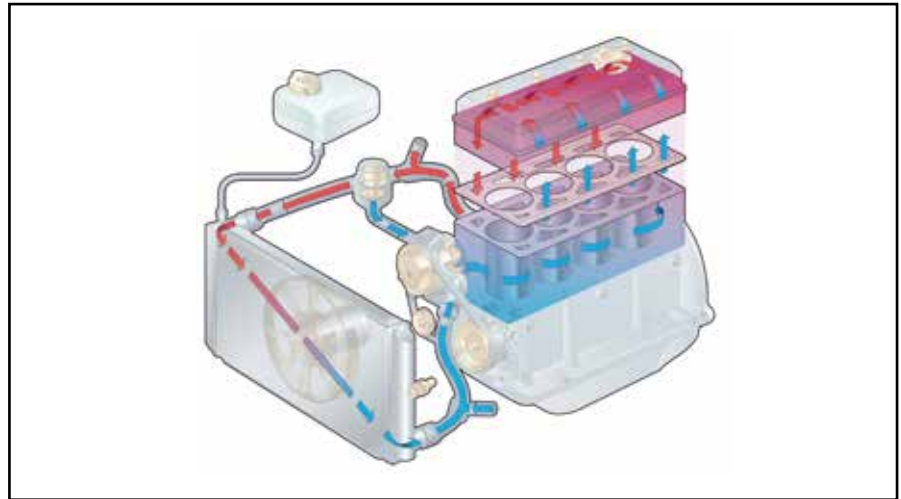

many circuits are pressurized.

This means that they can work at higher temperatures without the cooling liquid coming to a boil.

Pressurized circuits mean smaller radiators, better performance of the engine, but also higher temperatures; the materials of the entire circuit must be carefully chosen to withstand the

high temperatures of the pressurized circuit.

Provided with one or more radiators, with secondary circuits for heating the passenger compartment and in some cases also equipped with a circuit for the cooling of the turbine, the cooling circuits have the water pump at their centre.

1.4 Modern cooling system scheme

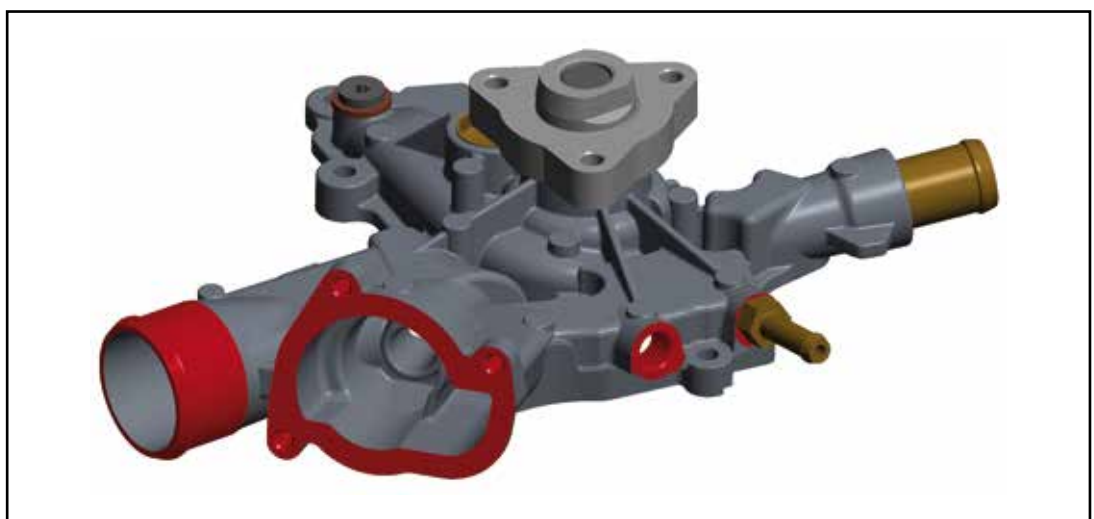

Operation of a water pump

Although in recent years, water pumps have undergone major changes related to changes in the engines onto which they are mounted, the vast majority of the water pumps have maintained a “classical” structure, where design rules have not undergone drastic changes.

There is always a mechanical drive, which is necessary to draw in rotation the shaft of the inner bearing to which the impeller is connected, which is the component that transfers mechanical

power from the engine to the fluid. The highly specialized components such as mechanical seal and the bearing are now highly industrialized,

made with high performance materials that have evolved over time to last longer and longer while withstanding higher and higher temperatures.

2.1 Water Pump with integrated thermostat housing

2014

Water Pumps, timing belt Kit with water pump / Pompe Acqua, Kit Distribuzione con Pompa Acqua / Pompes a Eau, Kit distribution avec Pompe a Eau / Wasserpumpen, Spannrollen Kit mit Wasserpumpe / Bombas de Agua, Kit Distribución con Bomba de Agua

It is thanks to the action of the impeller that the coolant is able to overcome the resistance of the cooling circuit (usually very tortuous), flow and therefore be able to transfer heat from the engine to the radiator, which in turn transfers it to the external environment (image 2.1).

Built in this way the water pump works from the first moment when we start the engine even when there is no real need to circulate the fluid. The only element that is able to ensure that no water passes through the radiator is the thermostat, whose housing can be located in the same body as the water pump (image 2.2).

Due to its construction technology, the thermostat is made in order to open the flow of the coolant towards the radiator only after it has reached a specific temperature; this prevents the coolant from being cooled when in fact it is not still necessary (for example,

when the engine is still cold). Taking power from the engine belt, or by other similar mechanisms, the water pump has the number of revolutions which is directly related to the number

of engine revolutions; this also means that the water pump works from the moment the engine starts even though it is cold, that is the reason for the presence of the thermostat.

2.2 Modern thermostat

Power take-offs

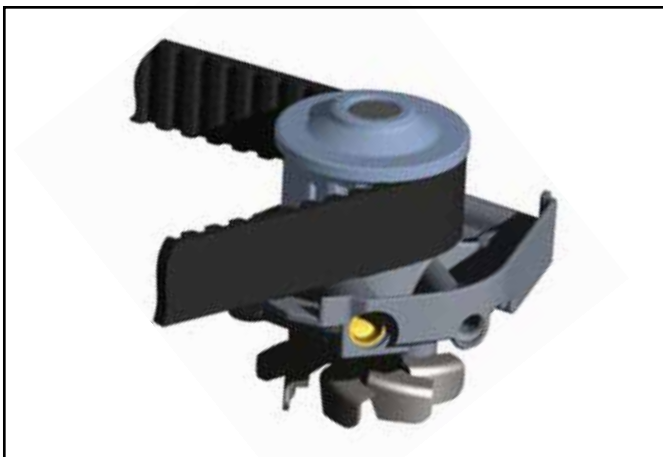

The drive of the water pump is mechanical; this means that the pump absorbs torque from the engine to rotate the impeller which circulates the coolant, in what way? In most cases, the pump has a pulley which is driven by a

toothed belt, it is generally the same belt that moves the camshafts of the engine (image 3.1).

In some cases, for reasons related to the route of the belt, the water pump has a pulley without gear teeth,

because the motion is transmitted only by friction with the back of the belt (image 3.2).

The use of the timing belt is not the only case in which the water pump receives power from the belt indeed there are

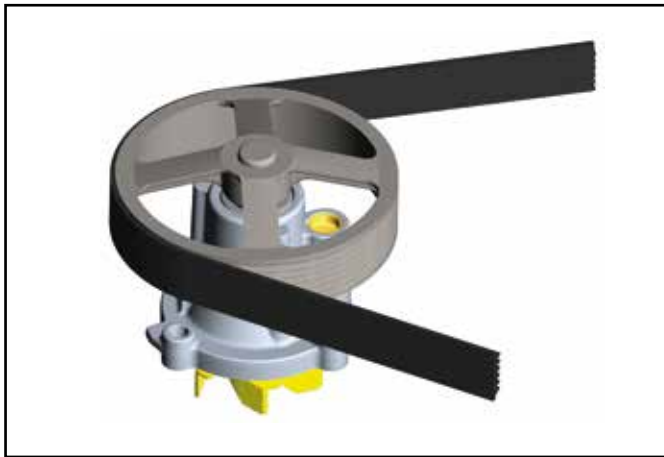

3.1 Water pump with drive on engine belt teeth

3.2 Water pump with drive on the back of the engine belt

a large amount of engines that, due to the layout of the various auxiliaries have a belt dedicated exclusively to all these services such as the oil pump, the power steering pump, the high pressure oil pump, the air conditioner compressor, and of course also the water pump.

In these cases the belts used to provide the power to services is of type Poly-V;

3.3 Water pump with a Poly-V power take off

quieter and easier to use than the toothed belt, is capable of ensuring a smooth operation at all speeds of rotation (image 3.3).

As design was now been abandoned the classical V-belt typical engine of a certain age whose performance has been widely surpassed by Poly-V belt.

The many different design choices that characterize modern engines are also

reflected in the water pumps, so much so that the solutions to power a water pump are not limited only to the engine belt (or to the poly-V belt when the camshafts are driven by chain). There are indeed a series of variants in which there is

an actual mechanical coupling that uses shafts with splined profiles (image 3.4).

The solutions that are actually used can be many (gears, drives the camshaft chain, etc.), but these are found in very few cases: engines of a certain size like those used for industrial applications (generators, etc..) or engines for industrial vehicles.

3.4 Water pump with drive by splined shaft

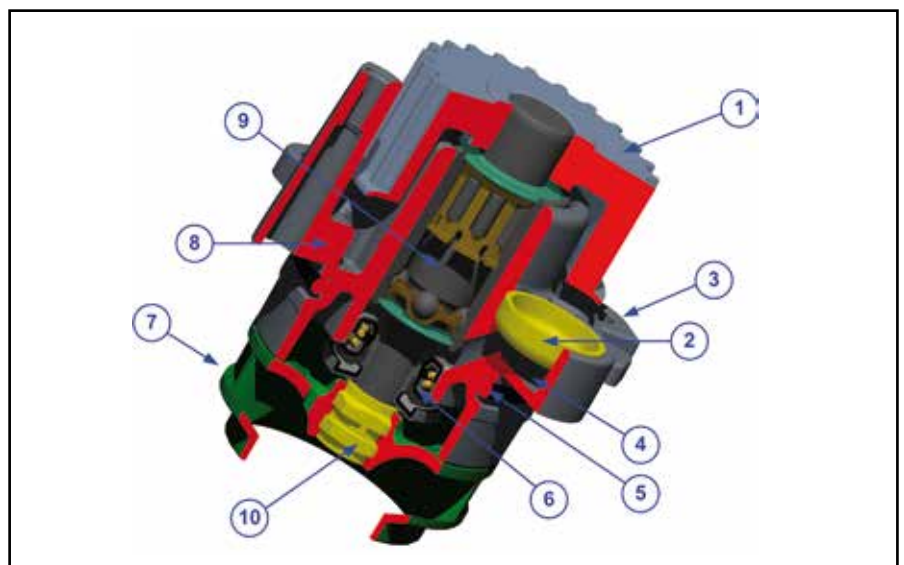

Section of a water pump: main components

Every water pump, however different it may seem, when reduced to minimal terms can be equated to a small number of principal components that perform the same function (image 4.1):

1. Toothed pulley for coupling to the engine belt and transmit motion
2. Cap of the tank that collects small leaks from mechanical seals, which are physiological
3. Hole, in the pump body, for one of the fastening screws to the engine
4. Tank to collect coolant leaks from the mechanical seal
5. O-ring seal in the assembly location of the water pump
6. Mechanical seal
7. Impeller, in this case made of techno-polymer, of the type with closed spaces

8. Main housing of the water pump, in this case made of die-cast aluminum

Water pump design

The factors which contribute to literally give shape to a water pump are many: performance, reliability, durability, combined with the highest overall quality levels are the characteristics we seek in the development of all our products.

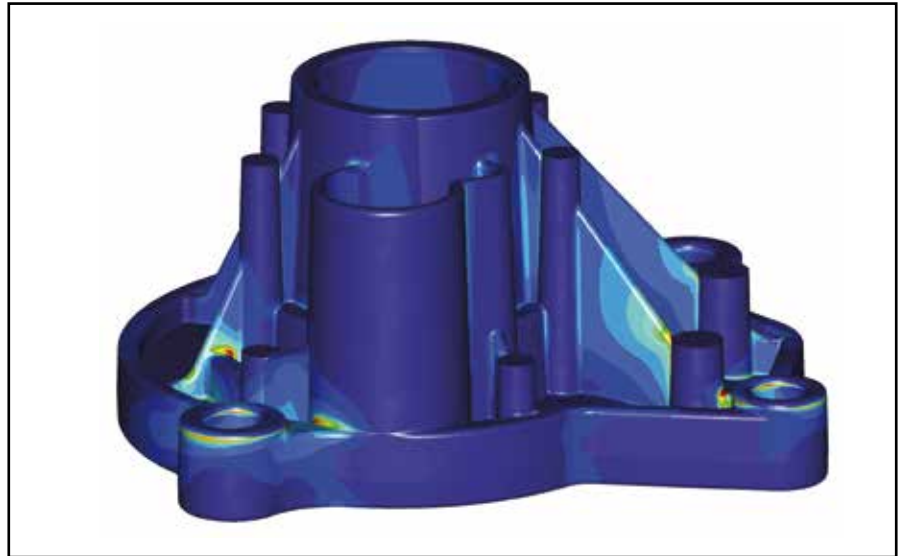

The geometry of the pump housing is the result not only of technical considerations, related to the stress to which the body itself is subjected, but also the result of the morphology of the entire cooling circuit.

Often the water pump is in the meeting point of the “secondary” coolant circulation circuits such as passenger compartment heating, cooling turbine, etc..

Inserted in the majority of cases in a space directly in the engine block,

the water pumps have to operate in a difficult environment; high temperatures of the coolant and the air under the

hood, together with the continuous vibration of the engine, is the usual work environment for a water pump.

5.1 Structural analysis of water pump housing

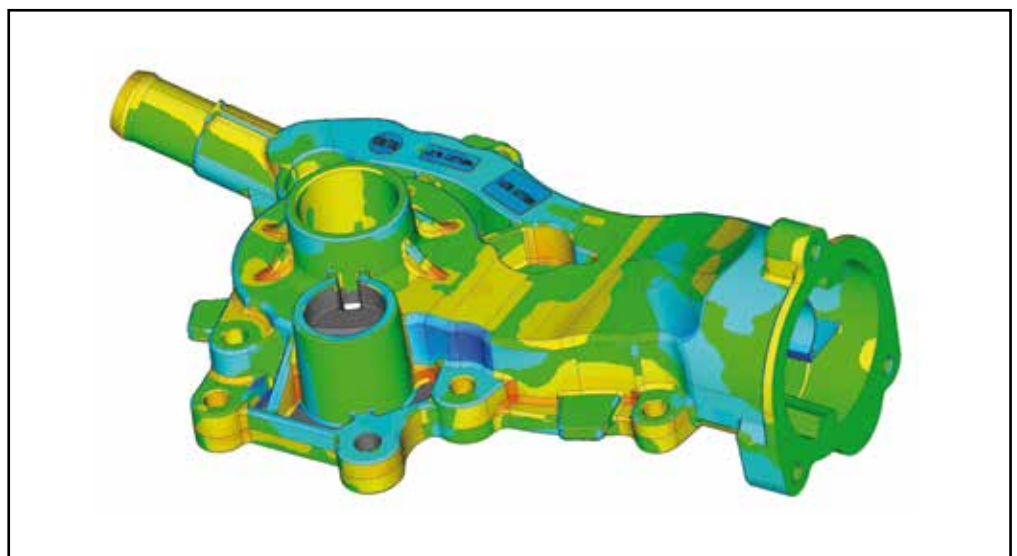

All this is reflected in a design process tailored to each specific reference. Every water pump is developed according to common design criteria refined during a business experience that has now reached half a century.

Finite element analysis is performed to ensure that water pumps, subjected to the worst combination of conditions, are still able to withstand the stresses while maintaining a further adequate safety margin (image 5.1).

Often a number of additional rotating masses are assembled on the water pump (viscous coupling units, fans, etc.); these masses may constitute an additional burden on the operating conditions of the pump (when these masses become eccentric).

This is a further aspect that must be taken into account when sizing; the presence of rotating masses, which can give rise to additional stress, is a source of considerable increase of the forces acting on the pump housing, added to those already present.

The strict observance of the size limitations of the project is another crucial aspect, a complete optical inspection conducted in 3 dimensions ensures that the geometry is consistent with the requirements in the design (image 5.2).

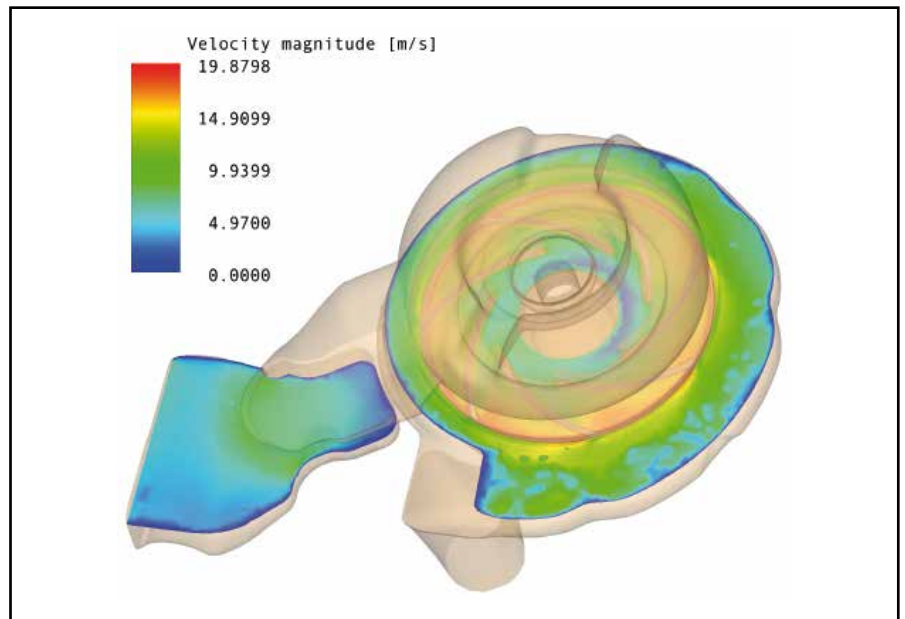

5.2 3D dimensional control water pump housing

Testing to ensure performance of the water pump

The main function of a water pump is to ensure the circulation of the coolant in each part of the circuit; this results in the fact that the pump must be capable of giving sufficient energy to the fluid to circulate inside all the pipes of the circuit. The water pumps have a rotation speed which is closely tied to the number of the engine revolutions, therefore variable, which means that the water pump must provide the adequate coolant pressure and delivery in every operating condition.

To achieve this the component that is primarily responsible is the impeller which, by absorbing mechanical energy from the shaft of the bearing,

6.1 Fluid dynamics analysis of a water pump

transfers it to the coolant in terms of kinetic energy.

The design of the impeller and the volute (when this is part of the water pump) is closely connected to the resulting fluid dynamic performance.

These performances are predetermined by our computational procedures; subsequently a 3D model of the impeller is created, sized accordingly and all the geometry in contact with the fluid (volute, ecc.); the latter is then verified by simulation programs.

Fluid dynamic analyses are carried out in order to validate the calculated geometry of the impeller and to have a performance prediction of the water pump in any condition considered to be significant for the project, including verification of the absence of the cavitation phenomenon in the worst working conditions (image 6.1).

Once the calculations and simulations have given indications on the quality

6.2 Water pump prototype with components made of resin

of the geometry, the whole is physically realized by means of rapid prototyping techniques, which allow obtaining the physical components in a special resin, starting directly from the 3D CAD model without the need for any of the traditional production tooling (image 6.2).

For each water pump intended for a performance test, special tooling is developed, based upon fluid dynamics calculations, whose purpose is to allow the impeller to operate in the correct conditions, only in this way the tests performed give

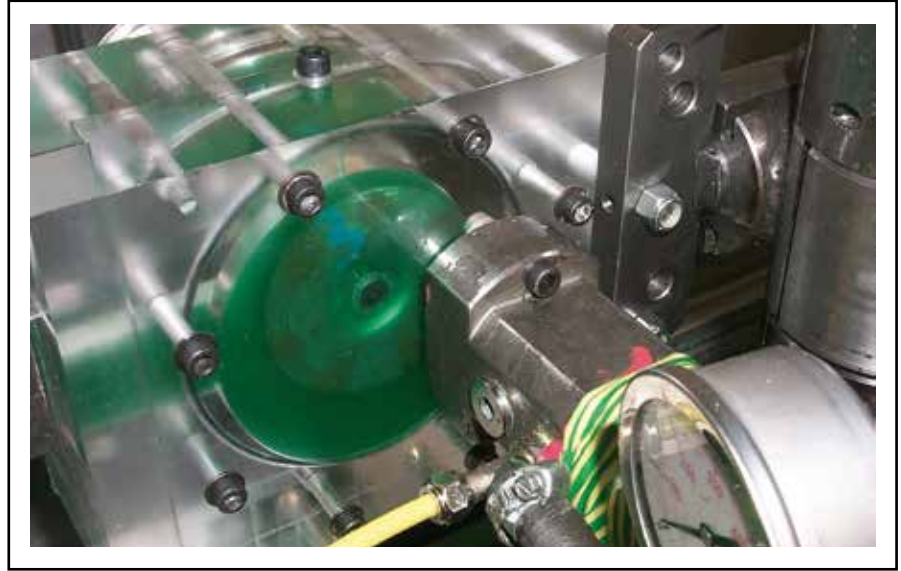

6.3 Flow rate test fixture

reliable results (image 6.3).

The ability of being able to verify the occurrence or absence of certain particular phenomena is extremely important, for this reason the test fixtures reproduce, in an extremely accurate way, the working conditions

that the pump will meet once assembled in the engine (image 6.4).

Real tests, carried out under strictly controlled conditions on our test benches, all undertaken directly according to our specifications, provide the evidence of the ultimate

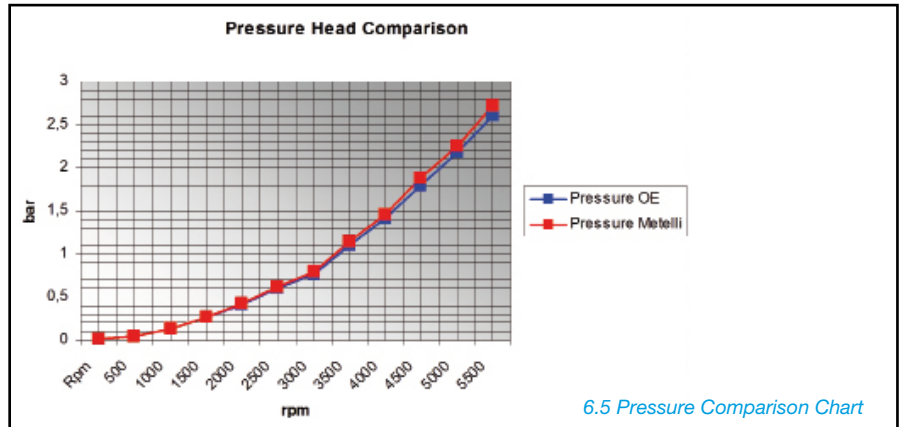

6.4 Transparent test tool

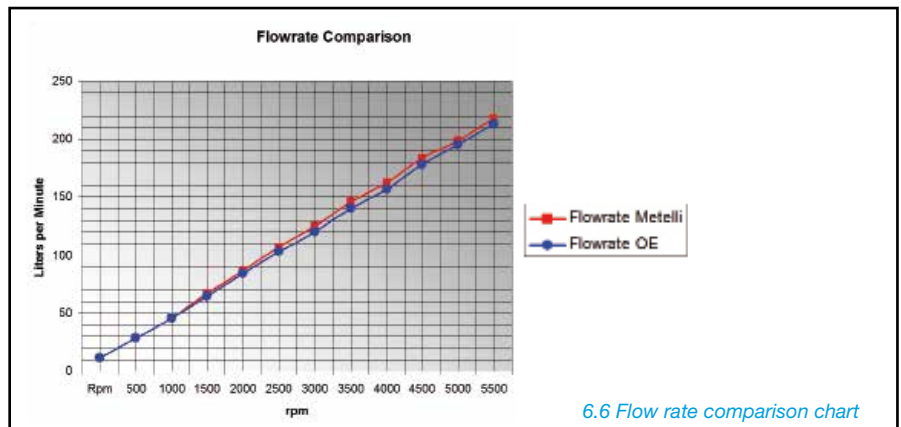

success of the entire design process. This assures us of the actual achievement of the hydraulic performance of our products in every possible condition of use (image 6.5).

The ability to validate and properly test the products is essential.

Thanks to our long corporate history, we have the in-house capability to perform an extensive set of tests at every level in order to fully characterize the hydraulic performance (and not only) of our products (image 6.6).

6.5 Pressure Comparison Chart

6.6 Flow rate comparison chart

The coolants

In the cooling circuit of the engine not only water is circulated! What is commonly called coolant is a mixture, in varying percentages (generally however is 50% -50%), of water and a substance composed mainly, but not only, of ethylene glycol.

The reasons for this particular mixture are multiple:

- Raising the boiling point beyond the normal threshold of 100 ° C at atmospheric pressure (in fact, pure ethylene glycol boils at about 200°C).
- Lowering of the freezing point well below the temperature at which pure water normally freezes

7.1 Impeller completely corroded due to incorrect fluid

(modern antifreeze fluids lower the freezing point to temperatures of -30°C and below).

- Increasing the specific heat of the liquid which allows, with the same rise in temperature of the fluid, to

remove a greater amount of heat.

- Inhibition of the corrosion processes that can be activated within the engine.

While on one side the ethylene glycol can influence a change in the boiling point, freezing and the capacity of the fluid to remove heat, the protection of cooling circuits from corrosion deserves a separate mention.

In the engine, and more generally in the entire cooling circuit, there are a wide variety of metals, each of these has its own chemical characteristics and, brought into contact with each other, can

7.2 Two different coolants

2014

Water Pumps, timing belt Kit with water pump / Pompe Acqua, Kit Distribuzione con Pompa Acqua / Pompes a Eau, Kit distribution avec Pompe a Eau / Wasserpumpen, Spannrollen Kit mit Wasserpumpe / Bombas de Agua, Kit Distribución con Bomba de Agua

trigger corrosion phenomena (image 7.1). The presence in the cooling circuit of a liquid that can contain chemical elements which favor this phenomenon leads to a rapid degradation of some components of the circuit itself (eg, head gasket, radiator) with consequent problems of different nature.

To avoid the onset of galvanic corrosion, modern coolants have special substances which act as oxidation inhibitors.

The presence of these substances gives coolants many properties that are useful to the motor (corrosion inhibitors, inhibitors of the deposit of incrustations, antifoaming properties, etc.) and are also the reason for which all liquids have their own particular color (image 7.2).

A mixture of water and ethylene glycol, would in itself be perfectly transparent, but these are colored by different producers because the presence of several inhibitory agents,

makes these fluids not always suitable to be used together.

The reason for this lies in the so-called bases of the inhibitors, which can be of three different types: organic, inorganic and mixed; these bases are chemically incompatible with each other and therefore, although the function of protection of the motor is the same, a liquid refrigerant must be used in the cooling circuit that is produced with the same type of base as the antioxidant agent.

The liquids, from the point of view of inhibitor additives they contain, can be divided into three main groups:

- IAT= Inorganic Additive Technology (with inorganic additives)
- OAT= Organic Acid Technology (with additives in organic acid)
- HOAT= Hybrid Organic Acid Technology (with hybrid additives)

The colour given to the different types of liquids serves precisely to avoid mixing liquids not compatible with each other which would lead to the formation of substances derived from chemical reactions and the effect of antioxidants and corrosion inhibitors would be annulled.

It must be underlined that every coolant manufacturer has adopted his own colour criteria, meaning that fluids of the same color are compatible only when they are from the same manufacturer!

Focus on main components

Each component in a water pump must perform a specific task and should therefore have characteristics according to clear requirements. Although the water pump, like any other mechanical member, is subject to normal wear, the use of high quality components, combined with a production process always under strict control, ensures a high degree of reliability and a long life product.

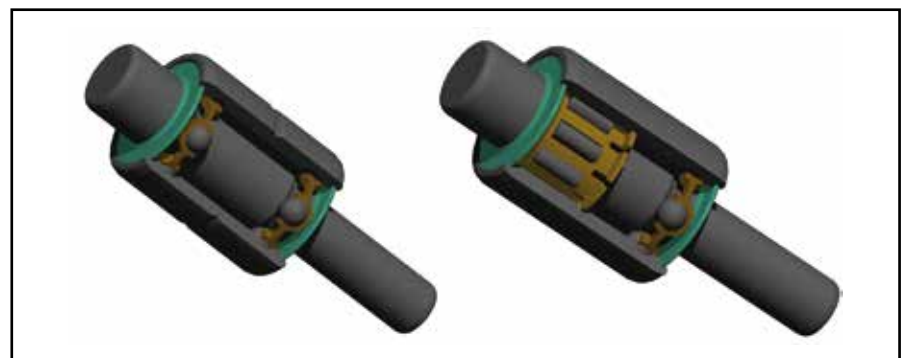

Before introducing a new component, our technicians perform selective homologation tests in order to ensure that the component's performance is in line with expectations, only after a successful result the component becomes part of the details that designers can use in our product.

Bearings

The bearings are directly responsible to withstand the loads coming from the belt tension. Created as a branch of the classical bearings in common use, water pump bearings have been designed on specific dimensions, and are made to last as long as the expected

life of the water pump, without being subject to any maintenance.

Manufactured already containing the right amount of long-life grease and the rolling elements protected by sealing rings against both grease losses and the infiltration of water and dirt, modern

8.1 Ball-ball and roller-ball bearing

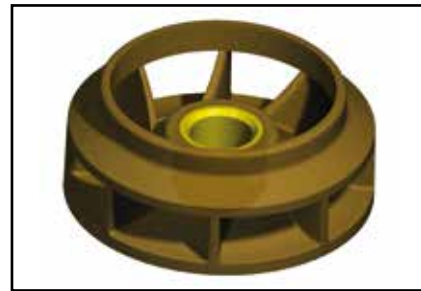

water pump bearings, once mounted in the water pump, do not require any maintenance.

They are assembled by interference in the housing and the accurate control of tolerances of the coupling, together with the real-time monitoring of the assembling forces, ensure an optimal fit with the proper maintenance of the radial clearance of the bearing (*image 8.1*). Made according to two main types of construction, they differ in the entity of load they can withstand.

The bearings designed to withstand higher loads, have in fact one of the two crowns of rolling elements consisting of rollers instead of the normal spheres; this allows increasing the contact surface between the rolling elements (the rollers) and the other parts of the bearing and therefore increasing the forces that the bearing is able to withstand.

Impellers

The impellers are the components that actually ensure the hydraulic performance of a water pump; they are specifically designed and manufactured to ensure adequate pressure and delivery to the engine where the pump must go.

8.2 3D model of a water pump impeller

8.3 Impellers manufactured in different ways

The geometry of each impeller is the result of precise calculations, it is CAD designed in the smallest detail and the performance is verified on our test benches (*image 8.2*).

Made with technologies ranging from sheet metal (including stainless steel) punched and drawn, to die-cast brass, cast iron and even the most modern engineering plastics, the impellers are produced with technology considered to be the most suitable in order to obtain a component that offers the best performance possible, without ever compromising reliability (*image 8.3*).

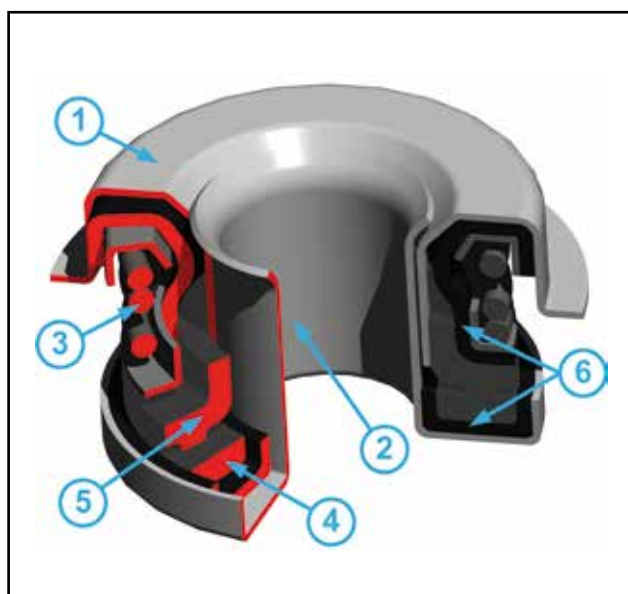

Such technical freedom, derived from an experience achieved in half a century, allows us to have great freedom of choice by identifying the most suitable manufacturing process in order to obtain the project geometry.

Mechanical seals

The modern mechanical seal is a highly industrialized component, compact and built entirely with top quality materials, it is the component that ensures no

leakages from the water pump.

Regardless of the technical solutions of details, the components that constitute the mechanical seal are almost always the same (*image 8.4*).

8.4 Section of a typical mechanical seal

1. Stationary part
2. Rotating part
3. Helical spring
4. Slip ring
5. Counterface
6. Bellows

It can have an apparently different shape, but the principle on which it is based is always the same. The development which it has been subjected to over the years, have led this to be more compact and have a greater duration; nowadays the mechanical seal is able to perform continuously even for many thousands of kilometers (image 8.5).

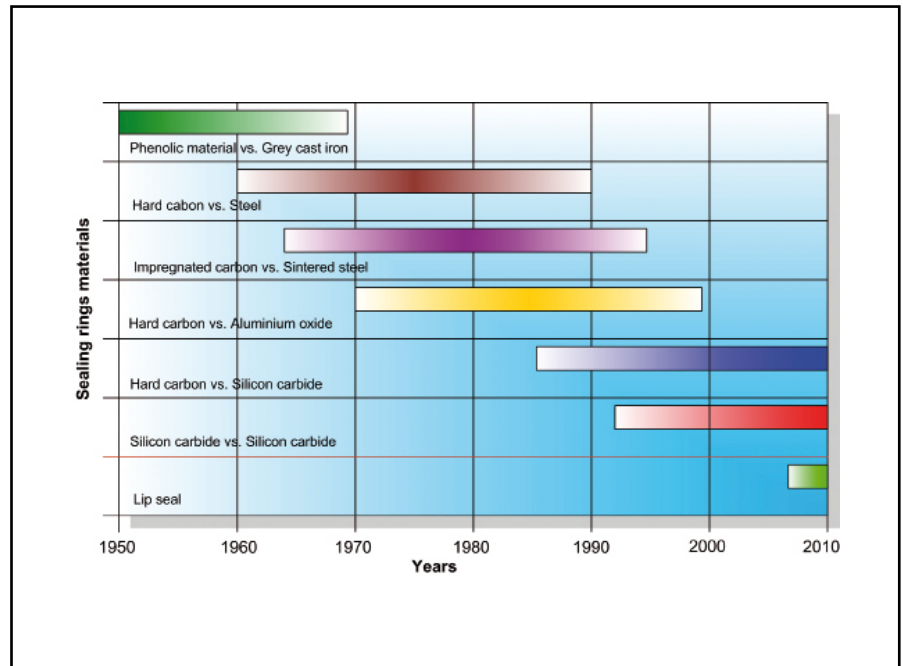

Extremely hard materials such as silicon carbide, which until a few years ago were considered “esoteric”, are

8.5 Some mechanical seals types

nowadays considered as being normal in the manufacture of slip rings for all high quality modern mechanical seals; this thanks to continuous efforts in the

development of the materials of these components (image 8.6).

8.6 History of the materials of the rings used in mechanical seals

Hubs and pulleys

The pulleys, which receive the mechanical power from the belt or in rare cases from the chain, are the components which actually keep the bearing shaft and consequently the impeller, in rotation.

The hubs perform the same function, they are used when, for design reasons, the overall dimensions of the pulley are greater than the area in which there are fixing holes of the water pump in its seat; from

the functional point of view they are considerable on a par.

Mounted by interference on the upper part of the bearing shaft, they must be properly secured to withstand the stresses that come from the engine belt (image 8.7).

The external geometry of the pulleys is according to strict tolerances; only this way is it possible to guarantee the perfect coupling between the pulley and belt; this results in a vibration and noise-free operation and a belt life in line with the highest standards.

8.7 Hubs and pulleys for the water pump

Pump housings

The main housing of the water pump, made in the great majority of cases in aluminum alloy, must simultaneously fulfill several duties.

- It must be able to withstand all the mechanical stresses.
- Casting must be perfectly airtight because the housing is an integral part of the cooling circuit.

8.8 3D model of a water pump housing

- It must be correctly coupled with the interface on the engine base and must ensure a perfect seal of the fluid.
- It must hold the bearing and the mechanical seal properly with the correct tolerances.

It is without doubt the component that requires the greatest amount of skill in its development, because each pump is literally a case on its own (image 8.8).

Precautions and instructions for proper installation

The operations for installing a water pump in replacement to one at the end of its life, must be performed carefully, taking care to execute everything in the best possible way and not forgetting to do all the necessary checks in relation to components also directly related to the water pump.

1. Always work in conditions of safety and respecting the environment.

2. Allow the work area to be accessible, if necessary remove the pieces in order to allow the correct access to the water pump area.

3. Keep strictly to any instructions from the manufacturer for the assembly of the water pump.

4. The cooling circuit must be drained completely, carefully cleaned and rinsed; particles present in the circuit

ruin the faces of the sealing rings, jeopardizing the functioning in a short time.

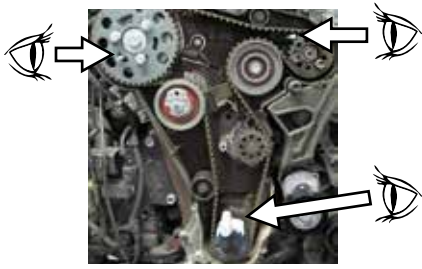

5. The coolant should be entirely replaced with a **new coolant, which will fully meet the characteristics required by the manufacturer.**

6. If the water pump is part of the distribution circuit, the first operation is **blocking the motor phase using any special tools devised by the manufacturer.**

2014

Water Pumps, timing belt Kit with water pump / Pompe Acqua, Kit Distribuzione con Pompa Acqua / Pompes a Eau, Kit distribution avec Pompe a Eau / Wasserpumpen, Spannrollen Kit mit Wasserpumpe / Bombas de Agua, Kit Distribución con Bomba de Agua

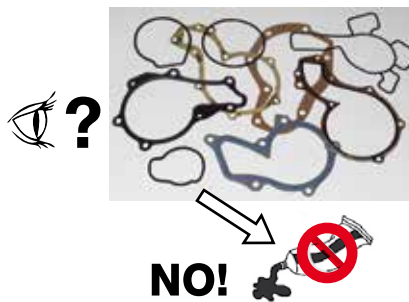

7. Once the pump has been removed, **the surface of the crankcase must be cleaned very well** from any residues of sealant and gasket pieces that have remained glued, so that the metal surface is perfectly clean, degreased and dried.

8. Before doing anything else check that the replacement water pump is interchangeable with the new one.

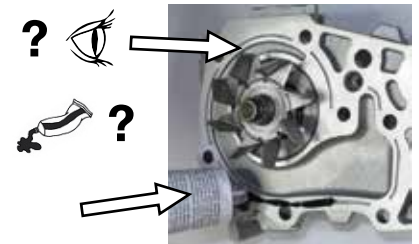

9. If the pump has a gasket, metal or other type, the sealing paste should **not be used**; the gasket supplied with the pump is adequate to ensure a perfect seal, make sure the mounting

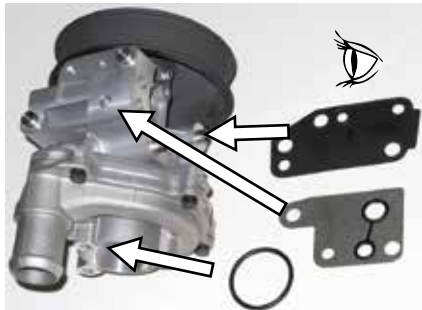

surface on the crankcase is perfectly clean.

10. In the case in which the pump is intended for an installation with sealing paste, always take care to use the correct amount only on the water pump surface **without using too much**; excess paste in fact often ends up in the mechanical seal causing leakages.

11. Each seal that has been removed should be replaced with a new one, never reuse gaskets used even if they seem in good condition.

12. The mounting screws should be tightened crosswise and, before tightening them completely, **you must ensure that the pump is centered correctly and can rotate freely in its housing.**

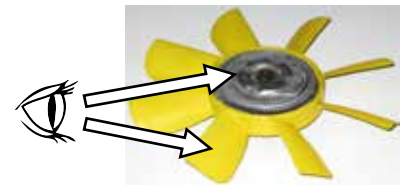

13. Strictly observe the tightening torque of the screws indicated by the manufacturer.

14. Always wait for about 1 hour with the cooling circuit empty to allow the sealant that is inside the volute to polymerize properly.

15. Check the good condition of any joint (viscous and other) mounted on the water pump and relative fans; when viscous joints with unusual clearances or bent fans or fans missing even only parts of a blade are found, replace them.

16. The hose clamps that have been removed should be checked and if necessary replaced with new clamps.

17. Concurrently with the water pump replacement, in addition to the belt, all components within the belt system must also be replaced (pulleys, rollers and / or cylinder tensioners and other parts related to the system).

18. Place the belt correctly following the manufacturer's instructions, especially when this concerns the timing belt, if special tools are required, use them.

19. Some water pumps have gears and spline shafts as drives; ensure the good condition of the gear

teeth and splines and have the foresight to put a small amount of specific grease on the groove before insertion into the housing.

20. Check the condition and the proper operation of the thermostat.

21. Check the operation of temperature probes.

22. Check the good condition of the cap of the expansion tank; it should not be clogged by various incrustations.

23. Cam Shafts must be locked before disassembling the timing belt otherwise it's needed to **restore the correct engine timing by carefully following the tasks recommended by the manufacturer.**

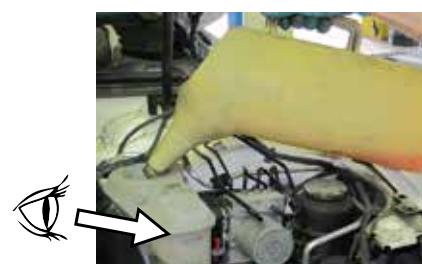

24. Tighten the belt respecting the value recommended by the manufacturer; avoid excessive tension, allow the engine to run

manually and check that the position of the belt is stable; restore the correct tension if necessary.

25. To check belt tension use the appropriate instruments that are able to provide reliable data on the tension value applied.

26. Once the pump has been installed and the circuit re-sealed, ensure its first filling with a liquid coolant in compliance with the recommendations from the manufacturer.

27. Start the engine and leave it to idle, turn on the heating in the compartment and continue to refill the coolant from the highest point of the circuit (generally the expansion tank) until the level does not drop any more, wait for the opening of the thermostat so as to properly fill also the radiator.

28. Be sure to leave as little air as possible in the circuit before starting the engine; dry operation even for a few seconds of the water pump can ruin the mechanical seal, causing a subsequent noisy functioning and/or loss of liquid.

The most common damage to a water pump: causes and analysis

A preparation on the engine in the area that is intended to accommodate the water pump, together with the state-of-the-art execution of assembly operations, are the basic steps so that the pump, once in operation, behaves as expected.

Avoid making a series of common errors related to installation operations undertaken incorrectly, this leads to trivial but annoying drawbacks, such as.

Non suitable coolants

The use of unsuitable cooling liquids can not only create problems to the

engine from a thermal point of view, but even worse, does not protect from corrosion that can arise in the entire circuit. This is due to a corrosion of

10.1 Rusted components due to unsuitable coolants

the circuit metals, according to their chemical aptitude; the result is a rapid degradation of all the surfaces of the cooling circuit.

The use of unsuitable coolants, polluted or contaminated by particles, in addition to corrosion, leads to the limited duration of the mechanical seal.

Leaks of liquid accumulate close to the bearing, often causing the leakage of grease and the consequent bearing failure (images 10.1 and 10.2).

Air bubbles remaining in the circuit

It is very important to completely eliminate air bubbles from the cooling circuit. Residual air bubbles that cannot end up in the upper expansion tank make the circuit, at best, work with reduced section; the presence of air bubbles that are not removed can compromise the correct operation of the water pump (image 10.3).

10.2 Mechanical seals damaged by unsuitable coolants

10.3 Sign of operation with air trapped inside

Overheating

When air occurs in substantial amounts in the circuit, the mechanical seal works dry; this has as the initial effect of mirror-polishing the surfaces of the sealing rings causing subsequent leakages, and if the phenomenon

lasts in time the heat developed is such as to melt the rubber parts of the mechanical seal and also leave a trace of the heat on the pump housing itself

(image 10.4).

10.4 Surfaces with signs of overheating

Unbalanced viscous coupling unit

It is important to make sure that the viscous coupling unit is in good condition before reassembling it on the water pump. A viscous coupling unit with a damaged bearing rotates unbalanced and therefore represents

10.5 Damaged viscous coupling unit

a high stress that is added to the belt tension. This easily leads to water pump bearing failure (image 10.5).

In the cases of more serious imbalance, the stresses reach values so high as to cause even the breakage of the pump housing (image 10.6).

Replacement of other components of the drawing system

The great majority of water pumps are driven by a belt, distribution or service. The first thing to do is a careful inspection of the belt, if it shows signs of wear or aging of the material (cracks in the rubber, shiny surfaces, etc.), must certainly be changed. When replacing

the water pump it is always preferable to replace the pulleys and idlers also, as when they malfunction they are often the cause of water pump bearing failure as a result of an overload in the belt tension (image 10.7).

10.6 Complete failure of the pump casing due to unbalanced masses

10.7 Idler and tensioner pulleys

2014

Water Pumps, timing belt Kit with water pump / Pompe Acqua, Kit Distribuzione con Pompa Acqua / Pompes a Eau, Kit distribution avec Pompe a Eau / Wasserpumpen, Spannrollen Kit mit Wasserpumpe / Bombas de Agua, Kit Distribución con Bomba de Agua

Bearing overload

The belt tension with load values beyond those recommended is due to working conditions of the bearing being particularly severe. The result is a life of the component that is extremely reduced and in some cases it leads to a complete failure thereof (images 10.8 and 10.9).

10.8 Bearing shaft damaged by excessive load

10.9 Bearing components damaged due to overload

Improper use of sealing paste

The use of sealing paste, is expected on some references, and on these should be used in the correct way. Specific products should always be used, never generic or other sealants and it is equally important that they be used in the correct amounts. The use of improper sealants or worse still, used in excessive amount always causes problems, the accumulation of sealant residue that ends up in the mechanical

10.10 Improper use of sealing material

seal causes immediate leakages and there may be lumps of hardened sealant that end up in the pipes of the cooling circuit (image 10.10).

If a water pump has been provided with a metal gasket, O-rings, or other, this solution is sufficient to guarantee the seal; sealing paste should not be applied, it would only jeopardize the operation of the gasket supplied with the part (images 10.11 and 10.12).

10.11 Sealant paste incorrectly applied on metal gasket

10.12 Sealant paste Sealant paste incorrectly applied on O-rings

Improper installation

It is important that the water pump assembly operations in the housing are done properly, carefully following any special instructions attached.

An installation performed incorrectly can easily bring the water pump to work badly or even worse can damage some sensitive components such as

seals, or in some cases even the water pump housing itself (image 10.13).

10.13 Damage caused by incorrect installation

Assembly of components on the water pump

Some water pumps carry other components that must be installed after the water pump has been assembled on the engine. Correctly executing the assembly operations of these components is crucial; in particular it is extremely important to absolutely avoid hitting the bearing spindle, this would damage the sliding grooves of the bearing balls and in some cases could even break the shaft itself (image 10.14).

10.14 bearing shaft broken due to incorrect assembly operations

2014

Foreign objects in the circuit

Perform an accurate cleaning of the entire circuit when replacing the water pump. It is possible that there are foreign objects inside the housing space which, when they are moved by the coolant flow, can cause considerable problems.

When the impeller encounters a foreign object it is irreparably damaged, creating potential problems not only to all the cooling circuit, but it is possible that damage will occur even to the timing system (*image 10.15*).

10.15 Impeller damaged by foreign object in the circuit

Trends

Never before in recent years there has been a process of innovation related to this component, whose design criteria have remained unchanged for decades.

The need to reduce fuel consumption and emissions, the need to reduce the weight of components, the longer life required from products, have led to changes in water pumps in many of its aspects and have spawned a whole new generation of water pumps, born with entirely new design concepts.

Materials

Besides the materials considered more “traditional” such as die-cast aluminum for pump housings, we are

witnessing an increasing introduction of polymers. Materials similar to those now used in impellers have, in recent years have been increasingly used in the construction of the water pump housing (*image 11.1*).

Characterized by a light weight, good dimensional stability and good chemical compatibility, the introduction of these materials in the water pump housing is still limited to a small number of references.

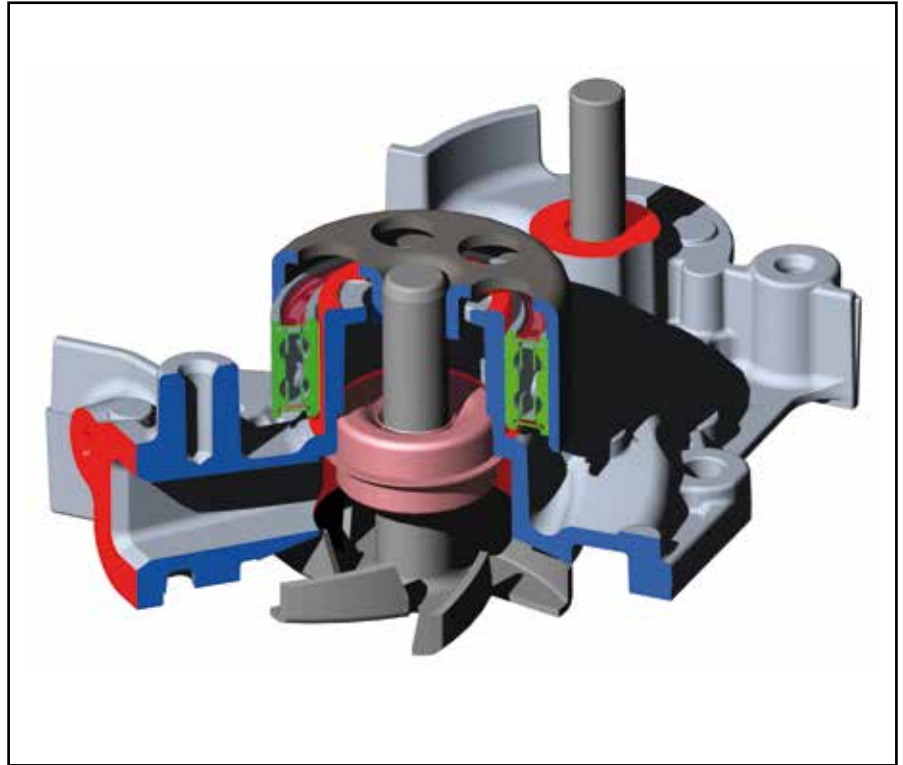

11.1 Pump housing made of thermosetting material

Bearings

Along with specific water pump bearings that the market has been used to seeing for many years, due to continued increases in power that the engines undergo during their life on the market, belts are more and more stressed and have led to the introduction of a new generation of bearings, more similar to the bearings we find in the air conditioner compressor pulleys (image 11.2).

Unlike bearings assembled inside the pump housing, these bearings are to be mounted externally to the housing; this allows having a larger bearing which is able to withstand higher stresses and thus to guarantee a trouble-free operation also with those motors which during their development have seen considerable increases in the values of the belt tension.

11.2 3D Model of Water pump with bearing (green section) outside the housing

Mechanical seals

The monobloc mechanical seals have evolved steadily over the years in the geometry and materials employed especially in sealing rings; this progress has made them more compact and more durable at the same time.

Recently an entire generation of newly developed mechanical seals has made its appearance on the market (image 11.3). More similar to oil sealing rings than to the classic mechanical seals, this new generation of components has the seal along the bearing shaft surface.

Provided with a higher resistance to dry operation, and a lower resisting torque, these are seals that use innovative solutions and materials and due to their geometry their dimensions have been really reduced to the minimum.

Solutions

The development trends of today are bringing onto the market a wide range of newly designed water pumps, whose purpose is to meet the new needs of pumping efficiency and reduce engine emissions. Due to its natural characteristics, a traditional water pump is designed to dissipate heat from the engine when it is operating at maximum performance. This type of operation is, in the real condition of engine usage, not very common; for an automotive engine top performance is requested from the engine less than 10% of his entire life.

The solutions that the designers have developed to meet the need of having a water pump that is adequate for proper engine cooling, but more optimized to meet the multiple needs of a modern

12.1 Section of the switchable water pump patented by Metelli

engine, are very different.

These solutions have led to a new generation of water pumps that are 'switchable'. This innovative model, even though it is still driven by the belt, allows the flow of water in the cooling circuit to be interrupted in different ways: by closing the pump lines, or by disconnecting the pulley and blocking the rotation of the impeller.

Metelli has optimized its product line, introducing an innovative, EU-patented solution – the most reliable on the market today.

This solution makes it possible to interrupt the flow of liquid in the cooling circuit thanks to a pneumatically activated gate valve.

The gate valve is actuated when a depression is created in the 'vacuum chamber' of the pump. The name of this chamber reflects the fact that the depression produced by the vacuum pump of the brake servo is used.

From the outside, the switchable water pump resembles an ordinary water pump with a slight enlargement in the area where the bearing is located. Here, in this enlarged area, is the entire mechanism responsible for actuating the gate valve around the impeller.

This mechanism is potentially harmful for the motor because it can interrupt the water flow in the cooling circuit. For this reason it was designed to be 'fail safe', that is to ensure the passage of fluid even if it malfunctions. One more way to guarantee the reliability of this innovative solution.

We are witnessing a true revolution in the way of designing a product that has remained fundamentally unchanged in 40 years.

These new approaches to the design of the water pump started to bring to the market a whole new generation of more sophisticated products, more efficient and with performances more

in line with the requirements of modern engines.
